ade the general duty of the Secretary of State de hospital services for both physical and mental but he is to entrust their administration to al hospital boards and local boards of management. regional boards are contemplated, and it is intended they shall enjoy a high degree of autonomy. There be no differentiation between teaching hospitals and r hospitals in the region : all are to come within framework of the regional organisation. Each onal board will be composed of people chosen by the retary of State for their individual suitability, but fore making the appointments he is to consult any iversity with which the hospital services of the area are associated, bodies representative of the medical profession, the local authorities of the area, and others concerned. Boards of management for individual hospitals or groups of hospitals are to be appointed by the regional board in accordance with a scheme drawn up by the board in consultation with the university, and proved by the Secretary of State. The scheme will ecify the hospitals which are to provide facilities for edical teaching, and each board of management is to nclude members appointed after consultation with the cal health authorities of its area, with the executive uncils for general-practitioner services in its area, with the senior medical and dental staff of the hospitals concerned, and with the governing bodies of any voluntary hospitals that are to come under the board. The board d management of a teaching hospital will include ominees of the university and teaching staff. The Bill places a specific duty on the Secretary of State to make available for medical education such facilities as he considers necessary to meet all reasonable requirements, and these duties will devolve on regional boards and boards of management. In addition there is to be a medical education committee in each region, to advise the regional board. This will consist of members appointed by the universities concerned, with an equal number appointed by the regional board : and representatives of other bodies, such as the Royal Medical Corporations, will also be included where appropriate.

A main feature of the general-practitioner services is to be the development of health centres designed for general medical and dental services, for many of the special services of the local health authorities, and for outpost clinics of the hospital and specialist services : they can also be used as bases for health education. The Bill makes it the duty of the Secretary of State to provide, equip, staff, and maintain the new health centres, and though he is empowered to delegate this function wholly or partly to local health authorities, the summary issued with the Bill (Cmd. 6946) explains that "it is not intended to exercise this power widely in the early years of the new service."

The Highlands and Islands (Medical Service) Grant Act is repealed : so the Highlands and Islands Medical Service will lose its identity, becoming merged in the general framework. The disappearance of this distinctive Scottish service will occasion regret north of the Border.

THE KING'S SPEE

In opening Parliament last Tuesday the KING that his Ministers recognise that the housewives of the nation have had to bear a specially heavy burden because of the shortages of houses, of foodstuffs, and of other consumer goods. It would be an urgent task in the new session to encourage an increase in the productivity of industry so as to raise the standard of living at home and expand the export trade. All necessary action would be taken to enable the school-leaving age to be raised next April. Legislation would be introduced for nationalising inland transport services and electricity supply, for the better organisation of a number of important industries, for the establishmen of a Ministry of National Defence, for the continuatio of national service, for dealing with compensation and betterment in relation to town and country planning, and for empowering local authorities to operate civic restaurants. "My Ministers," he said, "will do all in their power to increase the supply and variety of food and to see that it is efficiently and equitably distributed," and "will prosecute with the utmost vigour the task of providing suitable homes," ensuring that those most in need of it have first claim on new accommodation.

FROM THE PRESS GALLERY

Danger of Winter Famine in Germany

In the House of Lords on Nov. 6 Lord SALTOUN asked the Government what was being done to deal with the famine now prevalent in the larger cities of the British zone in Germany. When he was in Germany three months ago he found that the lassitude of the people in the streets was so obvious that anybody who moved with any briskness immediately caught the eye. The older children showed sunken eyes, drawn faces, and shrunken legs, sometimes with sores which were probably due to anaemia. He saw young children with faces that he could have covered with the palm of his hand. In spite of the all-pervading limey dust the population was incredibly clean, but all the time he was conscious of a sweetish sickly smell. A doctor whom he consulted said that it might come from a derangement of the liver caused by hunger. It was clear to him that the people were suffering from an advanced stage of malnutrition ; he would call it famine. He was informed that there had been a considerable loss of weight amongst the population and that was borne out by his own observation. The population was incapable of a full day's work, and although men in heavy occupations were given supplementary rations many preferred not to work a full week because the ration did not compensate them for the expenditure of energy caused by the extra work. Young children got preferential diet and yet the infant mortality-rate had trebled in Hamburg over the figure in 1938. Hunger œdema was prevalent, and was as great among the better to do as among the manual workers. It was thought improbable that any mother could suckle her own children. Infectious diseases did not show any great increase, but tuberculosis had made enormous strides, especially recently.

Lord PAKENHAM, replying for the Government admitted that the food situation in Germany was serious The present ration of 1550 calories a day for the norma consumer, while sufficient to sustain life, was not sufficien to enable a man to undertake reasonable work for a lo period. It was about half the German pre-war consum tion, and a little more than half the present level of c own rations. None of us could feel complacent 23,000,000 people for whom we possessed any share responsibility were living at that standard. It wa heartrending affair, but it was a mess of the Ger people's own making. Nevertheless, it must be a cons preoccupation of the British Government to see Germany could be enabled to consume more, or at be prevented from having to consume less. There four ways in which the problem could be tackled. British zone could grow more food, and everythin being done to make that possible. The Britis could obtain more food from Eastern Germany. T Germany could obtain more food at the expense people of this country. The question of whether the British standard of living further in order Germany was perhaps the hardest moral issue

British Government had had to face, and the Government were reluctantly but absolutely clear that nothing more could be done in that direction at the moment. To attempt to solve the problem along those lines by our own actions and by our own direct assistance would be to attempt an impossible task likely to bring down this country and Germany in common ruin. In the long run the food situation in Germany would be cured by the recovery of food-production in the world. In the short run everything hinged on what could be obtained from overseas—much of it at the expense of the British taxpayer.

QUESTION TIME

Rheumatism Research

Mr. H. SUTCLIFFE asked the Lord President of the Council what was the estimated expenditure in Great Britain at the present time on research into the chronic rheumatic diseases; what proportion of this work was fostered by the Medical Research Council; and whether any increase or acceleration of such research could be achieved in the near future.—Mr. HERBERT MORRISON replied: I have no figures of expenditure from private sources such as the Empire Rheumatism Council and the Nuffield Foundation. Expenditure by the Medical Research Council directly on this problem is estimated at £3500 per annum at the present moment, but the figure is subject to considerable fluctuation as new lines of approach to the subject are opened up. It also takes no account of fundamental research of a more general kind which may indirectly throw light upon the problem.—Mr. SUTCLIFFE: Is the Minister aware that there is no type of disease in connexion with which further research is more urgently needed just now, and is not the contribution by the Medical Research Council altogether insignificant?—Mr. MORRISON: No, Sir, I do not agree. There is plenty of research being done otherwise, and the mere amount of money spent is not necessarily a guide to success. I have a feeling that probably the solution to this problem will be found some day by a sheer fluke when somebody is looking at something else which has nothing whatever to do with this particular problem.

Sir W. WAKEFIELD: Could the Minister arrange for greater publicity to be given to the very valuable work done by the Medical Research Council?—Mr. MORRISON: It is difficult to train scientists to adopt a proper and appropriate sense of publicity. I expect they get a bit frightened by the Opposition who object to any sort of publicity about anything.

Release of Army Doctors

Sir E. GRAHAM-LITTLE asked the Secretary of State for War if he was aware that doctors in the Forces overseas were suffering, as an example submitted showed, from uncertainty with regard to their release, occasioned by the issue at the end of 1945 of a Government statement reducing the ratio of doctors to 2 per 1000, which was contradicted by a later Army circular fixing the ratio at 2·75 per 1000; and if he would now inform the officers concerned of the actual position.—Mr. F. J. BELLENGER replied: The ratio of 2 doctors per 1000 troops was agreed under the conditions existing at the end of 1945 to enable the maximum number of doctors to be returned to civilian practice for the winter months. By that measure the Army alone was able to release 5600 doctors by the end of February. Present estimates, based on an overall cover of 2·75 per 1000 British troops, provide also for medical commitments other than those that can be considered a purely military responsibility and for military families overseas. The release programme for medical officers must depend upon the strengths and deployment of our Forces generally, and the dates for release of the various age and service groups are announced as soon as possible. The release of doctors is thus inevitably linked with the release programme for the Army as a whole, and whatever the percentage of doctors per 1000 may be, there must necessarily be some uncertainty for individuals until a definite programme has been announced. But there is no more cause for uncertainty in the minds of doctors than in the minds of any other members of the Forces.

Recruitment of R.A.M.C. Officers

Replying to a question, Mr. F. J. BELLENGER stated that he could not at present give accurate figures of the number of R.A.M.C. officers that will be required in the post-war Army. There were now 454 holding permanent regular, and 461 holding short-service, commissions in the R.A.M.C. After the end of the emergency the normal method of entry would probably be by short-service commission.

Letters to the Editor

THE REGIONAL BOARDS

SIR,—Now that the National Health Service has become law, it is generally expected that the M of Health will shortly proceed to constitute the regi boards. Your leading article last week is there particularly opportune, but I wonder if you are r in your view that the function of these boards is prim one of administration? It is true that, according to Bill, regional hospital boards will be constituted " the purpose of exercising functions with respect to administration of hospital and specialist services," it seems desirable to me that the boards should concerned with broad lines of policy and that t detailed administration of hospitals should be left the hospital management committees and to the ho committees of individual hospitals which, it is cle from the discussions in the House, the Minister inten to use.

I would suggest that the prime concern of the region board should be to organise a hospital and speciali service which will provide the best possible faciliti and treatment for patients, so that they can obtain complete medical service of the highest grade in hospitals readily accessible to them. If this suggestion be accepted it would follow that the primary qualification of the chief executive officer of this board should not be, as Mr. Power holds, his experience of hospital administration, but rather his intimate knowledge of the medical aspects of hospital care. Such a knowledge might conceivably be possessed by an experienced hospital administrator, but this is unlikely unless he is also a medical man. It is, however, possessed by some medical officers of health who, by virtue of their office, have also had considerable experience of administration; indeed it is even possessed by some clinicians, although it would probably be unwise to take them away from clinical work. The chief executive officer should have advisers in the more important departments of medicine, in nursing, and possibly also in administration. It would probably be an advantage if these were part-time appointments. In addition to these advisers it might be advantageous to have an advisory committee in each of the medical subjects for which there was an adviser, or the advisers could combine to form one such committee.

My idea of a regional board, therefore, approximates to the "alternative" plan of your correspondent and is based on the regional organisation of the Emergency Medical Service. The sector organisation of the Emergency Medical Service had in one respect an advantage over the regional organisation, since the hospital officer had less independence than the sector officer because he was on the staff of the senior regional officer. Senior regional officers, who were regular civil servants, were usually first-class administrators and splendid colleagues, but they had to supervise all the regional activities of the Ministry of Health. Moreover, they did not possess first-hand knowledge of running a hospital, either on its administrative or medical sides; yet, by nature of their office, they could over-ride decisions of the hospit officer except in matters of medical treatment.

One other advantage that the regional boards wi have is that they will be in a position to enforce their decisions on backward hospitals, whereas in the Emergency Medical Service the Ministry of Health only gave advice and a hospital could refuse to carry out the instructions of the hospital or sector officer. It speaks well for the hospitals of this country that the great majority accepted and loyally carried out the advice given them.

The chief executive officer will be appointed by the regional board, but the other key officer of the board—its chairman—will be appointed by the Minister. I would suggest that in almost every instance (perhaps in every one) the chairman should be a layman. There are experienced lay hospital administrators who could fill this position excellently, but in the majority of cases it would probably be wise to choose someone who had been chairman of a large voluntary hospital or of the hospitals committee of a large local authority. Such an ndividual would be well versed in hospital procedure, ut he should not be considered for the office unless e is also possessed of a judicial and well-balanced ind.

My views may not carry conviction either to my olleagues or the Ministry of Health, but I put them orward as a contribution to the discussion which your eading article seems certain to provoke.

Birmingham. LEONARD G. PARSONS.

THE SHACK PERIOD

SIR,—Your annotation of Oct. 12 (p. 534), discussing he Hospital of the Future, ends with the significant entence, "Meanwhile hospitals could be making use of he shack period to concentrate on personnel." Certain t seems that with time we shall have the walls and organiation—probably fine ones, too—but it is men, and not he walls or the forms, that are going to decide the ltimate standard of service. This theme was taken up oth by Sir Heneage Ogilvie and by Mr. George Perkins t the recent British Orthopædic Association dinner.

It is generally agreed that the development of the mind needs the constant sharpening of wits on one nother's whetstones. To see the work of others, to glean thoughts, the half thoughts from which so many others flow, is the best education for the doctor. Every progressive business man of substance is now sending his representatives abroad for that purpose. Surely it is time that this became part of the policy of the major hospitals.

The hospitals should not rely on and take advantage of the generous spirit and charitable heart of their staffs to keep themselves abreast at their own expense. A multitude of doctors, after years of work in the Services, find themselves financially unable to afford such travel. Rarely do they care to proclaim their financial embarrassment, and there follows the attitude of indifference, of laissez-faire; their spark of enthusiasm is smothered. Lambrinudi, in his wisdom, once remarked, "the trouble with doctors is that they are ashamed to admit that they are poor." The evening gossip columns, at regular intervals, delight in building up stories of the thousands of pounds those at the top of the tree are supposed to em; they utterly mislead the public. This is well reflected in the salaries now being offered for some of the leading professorial chairs. The senior judge gets, so I am told, something like £5000 a year; he merely interprets the law, has to decide on a few squabbles, and is perhaps occasionally called on to decide on the life of often a worthless individual. Whoever heard of such a salary being offered to our leading men? We must not forget that not only is such a leader responsible for a large number of lives, but, by passing on his hard-gained knowledge, he directly influences the happiness and life of thousands of others. There is no branch of any work as exacting as medicine, and Mr. Perkins, in addressing some remarks to the Minister of Health, made a very eloquent plea for a "decent" salary; not only for the actual work of the doctor, but to enable him to have regular holidays in comfort, and return refreshed in mind and body. The older the doctor the harder he has to work, for time then brings its reward; the business man, in his ageing days, can usually recline and be but a bystander.

At present practically the only opportunities for sponsored travel are those offered by the Medical Research Council; their funds, as everyone knows, are woefully limited, and they can support merely those travelling for positive research and who are prepared to devote themselves to a long full-time job. I would plead, therefore, that major hospitals change their attitude; that they pay and encourage their staff to attend congresses, send them to different hospitals abroad, and, of course, to those in their own country as well. There is always the smug attitude that we have done very well without such sponsoring. But that is not true. All our surgical giants travelled regularly; for their fees were heavy, their competition slight, and they could afford it. I remember Arbuthnot Lane saying to me in his later days, "I offer you two bits of advice—look after your health, and make it a rule to travel every year."

It may be said that hospitals cannot afford to pay for such travel. But that does not seem true, for I see vast sums of money being expended on the establishment of occupational therapy centres and all the luxuries of reablement. These are pleasing to the administrator or the superficial eye of visitors, but, as every surgeon knows, they are but meretricious tinsel unless there has been careful thoughtful primary surgery.

This war revealed that in the growing generation we have a brilliant young team: men with imagination—"the mother of fact," as Moynihan called it. It would be far better to send some of these men to travel than to bluff ourselves that these crowded pseudo-appointments, which many now have, are to their advantage. We must not overlook also that such travel does other things: it builds friendship and promotes understanding between nations, and one of the outstanding lessons of the war was the value of the personal contact.

May we hope, too, that in the selection of personnel for the hospitals a broad generous vision will come to be developed; men will not be picked for their willingness to pay lip service, for their possession of personalities unlikely to be competitive, or even because they have been registrars so long that it would be hard not to elect them. Obviously the guiding principle must be the type of service that they will be able to offer to the hospital. I hope, too, that the large hospital will not forget that their staff have a wider responsibility, a duty to pass on their painfully gathered experience to colleagues. That needs active support through the provision of funds for ample secretarial assistance, good photographic departments, a good follow-up system. It is not for these men merely to cull the thoughts of others—"pick the plums from other people's platters." They have a moral obligation to repay.

London, W.1. SOL. M. COHEN.

PSYCHIATRY IN BATTLE AREAS

SIR,—Those who have had experience at regimental aid-posts will confirm the opinion of Major Haldane and Captain Rowley (Oct. 26, p. 599) that there is no need and no place for refined psychological methods in forward battle areas. Unless a R.A.P. is cluttered up with casualties or much exposed to the enemy it is a suitable place for the treatment of anxiety neuroses. Common sense and a sound judgment of character are the main requirements ("psychiatric intuition" is perhaps the same thing), and even combatant officers who know the value of rest, reassurance, and listening to other people's troubles have often successfully treated or prevented battle neuroses.

Many patients suffering from acute anxiety never reach corps exhaustion centres. Those who are the least predisposed to neuroses react best to treatment at the R.A.P., and thus an unduly large proportion of the weaker types is seen farther back.

Records were kept of the psychiatric work done at the R.A.P. of a field artillery regiment over a period of ten months spent in battle—from the invasion of Sicily to the Anzio beach-head. It was usually not difficult to assess a patient's condition and decide what to do with him while he was still in a highly strung state. As a rule the men led the conversation to the source of their trouble and then betrayed themselves by emotional reactions (tremor, quivering voice, tense look, &c.). What mattered *most* was not the cause of their anxiety—this was easy to guess—but how they coped with it. Life in battle is uncomplicated and so are neuroses; it helped, however, that all men in the regiment were personally known before going into action.

34 manifest cases of war neuroses were seen during the ten months. Of these, 3 were evacuated without thorough examination because there was no time to deal with them; 12 were evacuated because they were considered unsuitable for treatment at the R.A.P. or because conditions were too bad for them; 5 were evacuated because they failed to recover in a few days, or relapsed; and 2 were sent to a psychiatric centre for a further rest after they had improved at the R.A.P.

12 patients were successfully treated with rest, reassurance, and sedatives, without evacuation from the regimental area; one of these was soon killed, but all others withstood the stress of further battle without relapse. The patients who were never seen by a psychiatrist make up a third of the whole series, but only one

of them belonged to the group which formed the majority of Haldane and Rowley's cases, and was described as having a "low anxiety threshold" and "low anxiety tolerance."

Of the 22 men evacuated to psychiatric centres only 6 returned to duty in the front line, and this includes the 2 patients sent back for more rest. This seems to confirm the opinion formed in the 1914–18 war that a patient's chances of recovery diminish with every move away from the enemy, though it may simply mean that those who were not likely to recover were selected for evacuation.

It might be worth adding one observation. Although the amount of stress various men could withstand varied greatly, three conditions contributed to the origin of all battle neuroses: (1) prolonged danger; (2) vivid impressions of the effect of enemy weapons (narrow escapes, wounding, the sight of casualties, &c.); and (3) physical hardship (fatigue, lack of sleep, hunger, cold, sickness, &c.). There were no manifest neuroses without all three causative factors, though one or two of them often gave rise to mild psychological upsets.

B.A.O.R. E. M. GLASER.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—In this correspondence the serious question of mistaken diagnosis seems not to have been raised. In most cases the clinical diagnosis is confirmed at laparotomy. In a few instances, however, not only is it found to be incorrect but the state of affairs is such as might well lead to disaster under a conservative régime. Most surgeons of experience must at some time have been deceived by a ruptured appendix exactly simulating a perforated ulcer. We have recently seen cases, confidently diagnosed as perforated peptic ulcer, which at operation proved to be ruptured appendicitis, perforation of the colon in carcinoma, in diverticulitis, and by foreign body, perforated Meckel's diverticulum, ruptured amœbic abscess, and ruptured ovarian cyst.

London. K. E. BOND.
Portsmouth. B. L. WILLIAMS.

SIR,—From the correspondence following Mr. Hermon Taylor's interesting paper of Sept. 28 it is evident that other surgeons have experience of the conservative treatment of perforated peptic ulcer. Moynihan, in his book *Abdominal Operations*, had no doubt that recovery by medical treatment alone was possible both in the acute and subacute forms of perforation. He records two cases under his care in which perforation had been diagnosed by competent medical men, and, operation being impossible because no skilled help was available, the patients were treated conservatively; the diagnoses were later confirmed by Moynihan himself at operation. Singer and Vaughan[1] in a paper entitled "'Formes frustes' type of perforated peptic ulcer" record their radiological discovery of gas under the diaphragm indicative of recent and unrecognised perforation.

In 1939 I first treated a case of perforated duodenal ulcer by conservative means, being encouraged to do so for the reason which later moved Mr. Taylor—because in previous cases I had often found the ulcer soundly closed by omentum or adjoining viscera. The first case was a man of 40 years, 2 hours perforated, who recovered without complications and left the hospital in 18 days. In 1939 and 1940 fifteen cases of undoubted perforated peptic ulcer were treated conservatively, with two deaths. The cases were entirely unselected and were those admitted under my care to the surgical wards at the Essex County Hospital, Colchester. Gas was found under the diaphragm on several occasions but was not a constant finding, nor did the amount of gas bear any relation to the severity of symptoms and the patients' recovery. The age of the patients ranged from 25 to 57 years and the length of the history from 2 to 24 hours, and the average stay in hospital was 18 days. The two fatal cases were over 50 years of age and both had been perforated 24 hours: the first died in 13 days from a subphrenic abscess, and the second died an hour after admission to hospital from shock. The patients were treated on Sherren-Ochsner principles without aspiration of the stomach, and except in one fatal case no resid abscess developed, but chest complications, includ atelectasis, were common, though not so severe as those cases submitted to operation. In this connex I would draw attention to the danger of precipitati pulmonary œdema by the injudicious administration intravenous saline, whether as part of conservati treatment or postoperatively.

There can be little doubt that in the past many medic men have treated perforated peptic ulcers by conservati measures, often without knowing the true state of affai One of my early cases was a general practitioner, wh under the impression that he was suffering from bilia colic, treated himself, and although the radiogra showed gas under the diaphragm such clinical improv ment resulted from heavy dosing with morphine that t patient would not countenance surgery, and he was n pressed to do so.

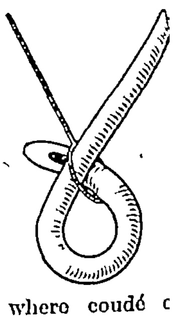
It is no longer my practice to treat *all* cases of pe forated peptic ulcer conservatively, but to reserve t new method for those cases where one can safely conclu that only a minor leak has occurred or where a leak threatened. If a recent meal has been taken the stoma contents are aspirated and continuous suction employe until there is evidence that the peritoneal reaction receding and the rent has closed. In the more severe cas the conservative régime is used and supplemented by small laparotomy under local or skilled general ana thesia, preferably with gas, oxygen, and curare. Th does the operation take its place in the planned campai of treatment. The exclusively conservative treatment all cases demands the finest clinical judgment on t part of the surgeon and may be the cause of profou anxiety to all those in attendance.

Mr. Taylor's paper records an advance in the manag ment of perforated peptic ulcer and confirms the exper ence of other surgeons, but the prudence of Prof. Gre Turner, as expressed in his letter of Nov. 9, demands, always, the highest regard.

Colchester. RONALD REID.

SUPRAPUBIC PROSTATECTOMY

SIR,—I was interested in Mr. Lane's description a method of procuring curvature in a catheter (Sept. 14, p. 398). Over 35 years ago my quondam chief, the late Colonel Damer Harrison, used to thread the end of the gum-elastic catheter of those days twice through the eye of the metal stylet, after which, using the latter as a holder, he plunged the catheter into very hot water for a few seconds and then into cold water. This resulted in the catheter acquiring a degree of "temper" and a tendency to coil at the end, and greatly facilitated its passage where coudé bicoudé instruments had failed.



Public Health (Tuberculosis)
Department, Liverpool. JOHN P. CLARKE.

CARCINOMA OF PROSTATE IN ANIMALS

SIR,—In his article of Oct. 19, Mr. Fergusson states in regard to ætiology, that "Unfortunately the rarit of prostatic cancer in animals has so far prevented an confirmatory investigations." Veterinary publication undoubtedly support this view, but, though it is true o the larger domestic animals, it is certainly untrue of th dog. For the last two years I have been treating prostati "cancer" in the dog with stilbœstrol dipropionate using the dose-rate first suggested in the human. I hav records of over 40 cases of prostatic disease, a fair propor tion of which are cases of gross prostatic hypertroph assumed to be carcinomatous. I hope to publish thes findings shortly in the veterinary press.

We have one great advantage over our medical con frères—that there is generally little difficulty in securing a necropsy in our cases. I have recently done necropsies on two dogs with testicular tumour (one was malignant with widespread abdominal metastases), and in both cases the prostatic tissue was negligible, resembling the prostates of castrated dogs. The feminising effect which

---

1. Singer, H. A., Vaughan, R. T. *Surg. Gynec. Obstet.* 1930, 50, 10.

produced with this lesion in dogs has been fully dis- ssed by Huggins and Moulder,[1] who suggest that these mours are Sertoli cell type neoplasms. The necropsy another case of testicular tumour which was operated (castrated) two years previously revealed negligible static tissue. In the entire series there was only e case where secondary metastases were demonstrated post mortem from a neoplastic gland and these were nfined to the inguinal lymphatic glands. I would ggest that in the dog there is a wide field for study prostatic disease which will no doubt have its lessons r human medicine.

Blackburn, Lancs. ALEXANDER H. HOGG.

PSYCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—Dr. Prestwich says that I wrote disparagingly five minutes' psychotherapy. In fact I made no ference to five minutes' psychotherapy in my letter Oct. 26, and his error of observation detracts from the lue of his testimonial to Dr. Beaton's methods.

May I try to make my main point quite clear? In lain language, I suggest that it is time to call a halt such irresponsible treatment of mental cases as that eported by Dr. Milligan: and by irresponsible I mean king due regard and respect for the personality of the dividual patient. The very pertinent questions and iticisms of the presentation of the material and of the nger of permanent injury to the brain voiced by Dr. oley and Dr. Mather remain unanswered, but I will pursue them, because even if all were fully answered y main objection would remain, as Dr. Atkin and Dr. edham have pointed out.

Both Dr. Prestwich and Dr. Milligan appear to hold at the sole aim of treatment with the psychoneurotic atient is the removal of symptoms: but it is much sier to remove the symptoms than to cure the disease. bucket of cold water, a painful surgical illness, or posure to war dangers will remove psychoneurotic mptoms in a considerable proportion of cases: a nger in real life can take precedence of a danger in e phantasy life (conscious or unconscious), and it is sy to believe that exposure to intensive electro- nvulsive therapy may be for many patients not s alarming than aerial bombardment. Dr. Milligan nores the fact that the symptom, inconvenient as it ay be both to the patient and those about him, is the tient's attempt to adjust himself to the circumstances his life. If, as Dr. Milligan believes, the intensive ectro-convulsive treatment obliterates entirely the ulty electrical patterns in the brain, it must leave e patient either without his former awareness of the sharmony of his life (i.e., mentally deteriorated), else having that awareness but lacking any means of aling with it, and so more miserable than before. these circumstances the treatment chosen may perhaps ve been the most beneficial and convenient for the ctor, for the relatives, and for the public who have pay for it, but certainly not for the patient: and such choice is, I take it, contrary to the accepted code of edical ethics.

The alleged "resynthesis of the personality" along correct lines" can only be described as a sheer pertinence. Dr. Milligan says that "it is of the utmost portance to adopt sound psychological principles in e rehabilitation and remoulding of the patient's rsonality during the recovery period. Mere obliteration psychologically unacceptable patterns of thought d conduct is not sufficient, and the resynthesis of the rsonality requires much care and judgment"—just e that. We are asked to believe that the quickly peated passage of an electric current through the brain raculously selects and obliterates permanently the faulty electrical patterns in the brain" responsible for acceptable thought and conduct, leaving intact fter the confusion has cleared) all the apparatus quired for normal function; and further that Dr. illigan or his psychotherapeutic colleagues have been le, writing as it were on blank pages, to remould along correct lines" the personalities of some 2500 erhaps not all ex-neurotic) of the inhabitants of the strict served by his hospital. Presumably they are re-created in the image of the A.M.O., or perhaps according to a specification drawn up by the staff. Can the flight from reason go much further?

Convulsive therapy seems likely to take a permanent place in the treatment of melancholia: intensive convulsive therapy as practised by Dr. Beaton may prove useful in a few desperate cases which would otherwise require leucotomy: but I hope the Board of Control will be able to ensure that, if any attempt is made to repeat this experiment in a hospital under their care, a competent and independent assessment is made of the personality of each patient before and after treatment.

London, W.1. J. NORMAN GLAISTER.

HERNIA THROUGH THE LESSER OMENTUM

SIR,—In connexion with Mr. Leon Gillis's report in your issue of July 13 of a case of hernia through the foramen of Winslow into the lesser sac of peritoneum, the following case is of interest.

A guard-man, aged 34, gave a history of 4 days' severe right upper abdominal continuous pain with periodic added colicky spasms. There had been retching, but only in the last twelve hours had he been sick. The bowels had not been opened for three days, but during this time he had been in bed in sick quarters. There was no relevant previous history. He had never had indigestion.

On examination he was extremely muscular and well built. The whole abdomen was guarded, but in the right subcostal region and the right iliac fossa there was well-marked rigidity. Intestinal sounds were present but subdued. Nothing abnormal was detected per rectum. Temperature 99° F, pulse-rate 104 per min.

A leaking ulcer was diagnosed, and under gas-oxygen and ether anæsthesia an upper right paramedian incision was made. There was free fluid in the abdomen, and grossly distended small intestine was traced to a hole in the gastrohepatic omentum just to the left of its free margin.

The orifice was stretched digitally, and a large loop of gut, in an early stage of strangulation, was drawn out of the lesser sac of peritoneum. A few moments' treatment with hot saline packs showed its viability, but an early ulcerated area, where the margin of the orifice had pressed on the wall of the bowel, required oversewing. Two stitches were used to close the offending hole in the omentum, and the abdomen was closed.

The patient made an uninterrupted and rapid recovery. Seen three months later, he was in good health and was returning to his unit.

It was thought that the hole in the lesser omentum may have been due to some trauma, but on questioning the patient closely after the operation no such history could be obtained. His main sport was tug-of-war, in which he pulled in a champion team, but it is difficult to see how this exercise would have caused a rupture of the affected omentum.

Leatherhead Emergency Hospital. STANLEY O. AYLETT.

TICK PARALYSIS

SIR,—A form of tick paralysis due to *Ixodes holocyclus* is of considerable interest and importance in the eastern coastal regions of Australia, causing paralysis and death among domestic animals and man. All domestic animals have been affected but dogs are the chief victims. There have been a number of human cases, some fatal (Hamilton, D. G. *Med. J. Aust.* 1940, i, 759).

In your leading article of May 25 you stated that "salivary glands have been suggested as the source of the toxin, on the basis of hypertrophy of the alveolar cells observed during engorgement; this mechanism has not been confirmed, although it would explain (as does the ova hypothesis) the incubation-period." Investigations in Australia by Clunies Ross (*J. Coun. sci. industr. Res. Aust.* 1935, 8, 8) and by Oxer and Rickardo (*Aust. vet. J.* 1942, 18, 194) have shown that the salivary glands of the tick are sources of the toxin. Glands taken from engorged ticks and injected into mice produce typical tick paralysis. This method has been used to determine the titre of antitoxic serum from immune dogs. This serum is used for treatment of cases of tick paralysis in dogs, and has been used with success in several human cases.

HUGH McL. GORDON.
McMaster Animal Health Laboratory, University of Sydney.

Obituary

EDWARD NEWBURY THORNTON

K.B.E., M.R.C.S.

Sir Edward Thornton, formerly chief medical officer for the Union of South Africa, whose death was announced in our last issue, was born at Sporle, in Norfolk, in 1878. Educated at Cheltenham College, he took the Conjoint qualification from the London Hospital in 1902, after serving as an assistant medical officer in yeomanry hospitals during the Boer War in 1900–01. In 1903 he returned to South Africa to serve as a medical officer in Cape Colony, and seven years later, on the formation of the Union, he was appointed medical adviser to the Cape provincial administration.

In the war of 1914–18 he served as medical officer in the South-West campaign before coming to England to command the South African Hospital at Richmond, where he introduced a vocational training scheme which was later extended to all military hospitals in the United Kingdom. For his services he was appointed O.B.E. in 1917, C.B.E. in 1918, and K.B.E. in 1919.

In the following year he returned to South Africa to take up the appointment of senior assistant medical officer for the Union and of director of the medical services of its Defence Forces. In 1920 he visited Nigeria and in 1930 Uganda to advise their governments on plague. Two years later he became secretary for public health and chief health officer of the Union, and he held these posts till he retired in 1936. But as chairman of the Peri-Urban Areas Health Board he continued to serve the Union, and during the last war, as acting director-general of medical services, he fostered the use of occupational therapy in its military hospitals.

Especially interested in housing and in social medicine, Sir Edward published, with Manfred Nathan, K.C., an extensive commentary on the public-health, housing, and slum Acts of the Union, which is widely used as a reference book. He also sponsored the District Surgeons and Midwifery Act, which enabled the Union government to subsidise these services and made it possible for local authorities to introduce and extend them, especially in rural areas. A man of personal integrity and honesty of purpose, he had a real interest in all things concerning public health and social welfare, and he achieved much in the service of the people of South Africa.

A. J. O.

LEROY UPSON GARDNER

M.D. YALE

Dr. L. U. Gardner, who died on Oct. 24, at the age of 57, had made himself a leader in experimental research in silicosis and had won an international reputation for his laboratory at Saranac Lake, in the Adirondack Mountains. Here, as director of the Trudeau Foundation, he was an outstanding figure among a famous team which included such men as Baldwin, Lawrason Brown, Heiser, and Sampson; and the little town owed much of its atmosphere of friendliness and earnest truth-seeking to his large-mindedness and integrity.

Born in New Britain, Connecticut, Gardner took his medical degree at Yale University in 1914, and after serving in the army medical corps he returned there as assistant professor of pathology in 1917. Two years later his long association with the Trudeau Foundation began when he was appointed pathologist at Saranac. In 1927 he became director of the Saranac laboratory and in 1938 director of the foundation. Three years before he had been awarded the Trudeau medal for his work on the pathology of tuberculosis and its relation to silicosis, and in 1940 he received the William S. Knudsen award for his research into the control of silicosis. In the same year Yale conferred on him the honorary degree of M.S.

Recalling a visit to Saranac, Prof. E. L. Collis writes: "Gardner had already embarked upon his research into the reactions of the human body to its environment, as exemplified by the inhalation of industrial dusts. First came silica, concerning which, although working independently of Kettle, he showed how, by animal experiments, whorled pulmonary fibrosis could be induced. Hardly a year passed without him giving further valuable additions to our knowledge on the pneumoconioses. He tackled asbestos dust and brought to light its toxic powers. Hard, resistant carborundum—carbide of silicon—followed, only to be found innocuo Then he studied the anthracosis of coal-miners demonstrated its entity. But probably his most re work on aluminium dust will be longest remembered his credit. Here was a metallic dust which he found only to be in itself harmless but to possess powers rendering the deadly silica dust innocuous if inha with it, and even to assist in its elimination from lungs if inhaled after the silica dust has already b deposited in the pulmonary tissues."

"Gardner gave the impression that he just could help being a great man, but never that he was striving eminence," writes A. I. G. McL. "In the States, wh dynamic personalities are common, he appeared indol by contrast—not with the indolence of a Sir Per Blakeney, but with the massive calm of a Red Indi brave. But despite this apparent inertia his output w prodigious and of first-rate quality. Tall and commanding in presence, friendly and humorous, he was the id chief because he always had time for the problems of h staff. I remember a 20-mile night drive with rattling ty chains at a temperature of 40 below to a medical meetin in another small town in the snow mountains. Th papers read at the meeting were diverse and patchy, bu Gardner summed them up at the end concisely with warm friendliness which must have raised the temperatur one or two degrees. His clear, strong, honest prose styl mirrored his mind, and he had no use for the long or redundant word. Only recently I heard two people say of one of Gardner's statements—'Well, if Gardner says so, it must be right.' I think the remark would have pleased him."

LUDWIG JULIUS BRUEHL

M.D. BERLIN

Prof. L. J. Bruehl, the well-known marine biologist, died at Muheza, Tanganyika Territory, on Oct. 11 after a distinguished and eventful career. Born at Breslau in 1870, he studied medicine at Berlin University, where he obtained his doctorate *summa cum laude* in 1893. From 1894 he was an assistant at the institute of physiology in that university, till in 1903 he was appointed to the newly founded Institute and Museum for Maritime Sciences in Berlin. There he built up the sea-fishery and other departments, becoming curator in 1909, a position he held until his retirement in 1930. During the first world war, while serving in a military hospital in East Africa, he was taken prisoner by the British in 1917 and repatriated under a Red Cross exchange system a month before the Armistice. In 1919 he was appointed to a chair at the institute and later became assistant director. He also held lectureships at the Landwirtschaftliche Hochschule and the Orientalische Seminar for tropical fishery. After his retirement he was appointed honorary professor at the Landwirtschaftliche Hochschule, but on account of his Jewish descent he was forced to leave Germany in 1934.

After he settled in Tanganyika his health began to fail, and in 1938 Hitler stopped his pension; but his fortitude and sense of humour remained firm.

Births, Marriages, and Deaths

BIRTHS

BINTCLIFFE.—On Nov. 8, at Birmingham, the wife of Mr. E. Bintcliffe, M.B.E., M.S., F.R.C.S.—a son.

BOLTON.—On Oct. 29, in London, the wife of Dr. Reginald Bolton—a son.

BOOG-SCOTT.—On Nov. 8, the wife of Dr. T. M. Boog-Scott—a son.

McLARDY.—On Nov. 4, in London, the wife of Dr. Turner McLardy—a daughter.

MARRIAGES

LOCKHART-MUMMERY—CRERAR.—On Nov. 5, in London, Hugh Evelyn Lockhart-Mummery, F.R.C.S., to Jean Crerar.

DEATHS

HOUGHTON.—On Nov. 7, at Farnham Royal, Bucks, Colonel George John Houghton, D.S.O., L.R.C.P.I., late R.A.M.C., aged 73.

HUXLEY.—On Nov. 5, Henry Huxley, M.R.C.S., of Shackleford, Godalming, aged 81.

KIRKLAND.—On Nov. 7, at Cheltenham, Robert Kirkland, M.B. Glasg., aged 88.

LINDSAY.—On Nov. 9, in London, John William Lindsay, M. Aberd., aged 71.

O'REGAN.—On Nov. 3, at Whitchurch, Glam, William Frankl O'Regan, M.B. N.U.I.

WILMOT.—On Nov. 6, Philip McKinnell Corbould Wilmot, M.B. Lond., aged 80.

Notes and News

PPOINTMENTS FOR EX-SERVICE SPECIALISTS

E new arrangements for increasing the number of alist hospital posts, which were outlined in a recent issue,[1] now been officially announced. The aims, according Ministry of Health circular (202/46), are to overcome the ulty of demobilised specialists who now cannot secure civilian appointments, and to obviate the risk of their o specialist service in the National Health Service. General itals in which the volume of work would justify an ase are invited to submit a proposal for the creation of tional posts for ex-Service specialists, at salaries of about 0 a year; if the proposal is approved the Minister will e himself responsible for the cost of salaries and emolu-ts until the National Health Service comes into operation. pitals are asked to seek the help of the appropriate ersity in the selection of candidates from the short list en by the hospital authority or governing body. For junior specialist the duration of senior B1 appointments, 550 a year, is to be extended; the scope for further itions to their number is restricted, but as far as possible are to be increased.

MEN AND MEALS

EASED perhaps by the adequate but uneventful feeding he past six years, Sir William Savage has been looking the diet of our remote ancestors.[1] They hardly seem ave done much better. The men of Java, Piltdown, and ing had characteristics in common with the apes—small rly developed brains, thick skulls, and teeth intermediate reen the stout weapons of the gorilla and the more modest tures now current. Their palates were large in proportion heir brain area, suggesting a crude not highly nutritious

ress at this time was probably slow in food habits, William suggests, as in everything else. "Man ate any-g he could get hold of and used sticks, stones and later ped stones as aids to kill animals. He ate his food raw chewed it well, giving up teeth as weapons of offence" ing rewarded for his forbearance by getting a lighter jaw. kind of feeding probably went on for something like a rter of a million years, by which time the old stone age e survivals of which linger in backwaters today) had n, and Neanderthal man, a brutal type, was occupying h of Europe. He had plenty of tools to help him to get d—axes, borers, scrapers, hammer stones, spears, assegais, s, and at last harpoons. He grew no crops, however, had no domestic animals bred in captivity. He used but no cooking pots; so as a cook he probably stuck to simple roast. But in the main his food was fish, fruits, bs, shellfish, and wild honey, all gathered with great ible. Food, indeed, was his predominant quest: a fish e would have been child's play to him; he was never of the next meal.

he last traces so far found of the old stone age date from t 10,000 B.C., while the earliest traces of the new stone are some 4000 years younger. In that short interval (as isation goes) man had taken a turn for the better in most gs, including his diet. Cave-dwelling Neanderthal man hought to be outside the direct line of ancestry of *Homo iens*, who now appeared, with his husbandry, his herds, fine cooking pots, and his use of copper. Stone tools, ground and polished, gave way without a break to bronze s and weapons; dogs, cows, sheep, goats, and pigs were t, and stalled in the pile-dwellings built in lakes. Barley, at, and millet were planted in the spring, and corn hers and mealing stones were used. Peas were cultivated, wild fruits used freely. These, with meat, fish, eggs of wild ls (no fowls were kept), milk, and honey made up a good ugh diet; the bronze age hardly improved on it, though domestication of the horse, better ploughs, hand-mills for ding corn, and more cereals—oats, rye, and winter wheat ust have made food-getting easier.

he balance of these ancient diets may not always have n very good; Sir William remarks regretfully how often grain-eaters in peaceful communities were overthrown by at-fed nomads with no settled habits. Too much cereal, points out, encourages dental caries and means calcium vitamin deficiencies, especially for children. He ends with some lively speculations about the ancient Israelites who, on one historic occasion, ate quails and died "while the flesh was yet between their teeth, ere it was chewed." The tired quails, he argues on good grounds, had fed thoughtlessly on hemlock before they were eaten in their turn.

Lancet, Oct. 26, p. 610.

rchæology and Food. Presidential address reprinted from the *Proc. Somerset Archæolog. Nat. Hist. Soc.* 1945, 91, 59.

University of Oxford

Four scholarships, each of £100 per annum, have been endowed by Lord Nuffield for women studying medicine at Oxford. The scholarships will be tenable during the pre-clinical course, and, in the case of women proposing to specialise in obstetrics, gynæcology, or ophthalmology, also during the clinical course.

University of Cambridge

The following degrees were conferred on Nov. 2:

M.D.—M. A. Rushton.
M.B., B.Chir.—J. W. Ker (by proxy).

University of Sheffield

Dr. D. R. Wood has been appointed lecturer in pharmacology, Dr. J. F. Goodwin research fellow and tutor in therapeutics, and Dr. Margaret H. Miller research assistant in medicine.

Royal College of Physicians

The Croonian lectures will be delivered at 5 P.M. on Tuesday, Dec. 3, and Thursday, Dec. 5, by Dr. H. L. Marriott, whose subject will be Some Quantitative Considerations regarding Depletion of Tissue Fluid and Blood Constituents. The FitzPatrick lectures will be delivered at 5 P.M. on Tuesday, Dec. 10, and Thursday, Dec. 12, by Sir Arthur MacNalty, who will speak on the History of State Medicine in England.

Royal College of Surgeons of England

A New Zealand industrialist has made an anonymous gift to the college for the endowment of a Commonwealth travelling professorship. The endowment will provide an income of about £2000 a year, and the benefaction is to be known as a gift from "a New Zealand Family." A Commonwealth professor will be appointed each year and will generally be a physician, surgeon, or scientific worker resident in Great Britain or in Australia or New Zealand. The appointing authorities are also empowered, however, to elect as professor a distinguished teacher from one of the other Dominions. He will be required to travel to Great Britain, or to Australia and New Zealand, or to any other Dominion, to assist in the advancement of medical science either by lecturing, teaching, or research.

Royal College of Physicians of Edinburgh

At a meeting of the college on Nov. 5, with Dr. D. M. Lyon, the president, in the chair, the following were introduced and took their seats as fellows:

Dr. A. M. Gillespie (Edinburgh), Dr. A. M. MacDonald (Edinburgh), Dr. R. A. Miller (Edinburgh), Dr. G. O. Horne (Edinburgh), Dr. R. J. Kellar (Edinburgh), Dr. G. D. Malcolm (Bridge of Earn, Perthshire), and Sir Andrew Davidson (Edinburgh).

The following were elected fellows:

Dr. H. J. Parish (Petts Wood, Kent), Dr. P. V. Pritchard (London), Dr. R. C. Wood (Edinburgh), Dr. P. N. Bardhan (Ferozepore, Punjab), Dr. H. M. D. Shepherd (Shanklin, I. o. W.), Dr. J. A. Malloch (Edinburgh), Dr. J. W. D. Goodall (I.M.S.), Dr. John Mackay-Dick (R.A.M.C.), and Dr. D. M. Anderson (Braintree, Essex).

The following were elected members:

Dr. Albert Rabinowitz (Johannesburg, S.A.), Dr. Andries Brink (Germiston, S.A.), Dr. Walter Henderson (Edinburgh), Dr. J. H. D. Millar (Edinburgh), Dr. R. H. M. Ross (Darlington), Dr. L. S. Prasad (Bihar, India), Dr. N. S. Gordon (Edinburgh), Dr. G. H. Armitage (Cumnock, Ayrshire), Dr. M. M. Whittet (Glasgow), Dr. Elizabeth M. Hislop (Edinburgh), and Dr. Ian Wang (Edinburgh).

The Cullen prize for 1946 was awarded to Lieut.-Colonel W. F. Harvey. The Hill Pattison-Struthers bursaries in anatomy and physiology were awarded to Mr. M. C. Berenbaum and Mr. James Jackson; and the Hill Pattison-Struthers bursary in clinical medicine to Dr. J. L. Quartey-Vanderpuije.

Royal Faculty of Physicians and Surgeons of Glasgow

At the annual meeting of the faculty Dr. G. B. Fleming was elected president; Mr. J. Scouler Buchanan, visitor; Mr. W. W. Galbraith, treasurer; Dr. A. L. Goodall, librarian; and Mr. Andrew Allison, representative on the General Medical Council. In addition to these office-bearers, the following were elected members of the council: Dr. John Gardner, Mr. A. B. Kerr, Mr. J. H. MacDonald, Dr. J. W. Macfarlane, Mr. E. G. Oastler, Mr. Charles Read, Mr. W. A. Sewell, Dr. W. R. Snodgrass, Mr. G. H. Stevenson, Mr. Matthew-White, Dr. J. H. Wright

Scottish Universities By-election

Mr. R. Scott Stevenson, F.R.C.S.E., has been nominated as Liberal Nationalist candidate. Mr. Walter Elliot, M.B., F.R.S., as already announced, is standing as a Conservative. The result will be declared on Nov. 29.

London Medical Exhibition

This exhibition, the 29th in the series, will be held in the new hall of the Royal Horticultural Society, Westminster, S.W.1, from Monday, Nov. 18, to Friday, Nov. 22. It will be open daily from 11 A.M. to 6.30 P.M.

Victor Horsley Lecture

Dr. F. M. R. Walshe, F.R.S., will deliver the seventh Horsley lecture at the National Hospital, Queen Square, London, W.C.1, on Wednesday, Nov. 27, at 5 P.M. His subject is to be the Contribution of Clinical Study to the Physiology of the Cerebral Motor Cortex, and Sir Alfred Webb-Johnson, P.R.C.S., is to be in the chair.

Chemical Society's Centenary

The Faraday lecture during the Chemical Society's centenary celebrations next July is to be delivered by Sir Robert Robinson, P.R.S., who is himself a past-president of the society. His work on electronic influences in organic chemistry is linked with the discoveries of Michael Faraday, in whose memory the lectureship was founded in 1867.

Medical Conference in West Africa

A conference is being held this week at Accra between British, French, and Belgian representatives, with Portuguese and Liberian observers, to arrange for the exchange of information and for coördination between the West African medical services.

Nuffield Scholarships for Gold Coast Officials

Scholarships in the academic year 1947–48 are to be awarded by the Nuffield Foundation to enable officers of Dominion and Colonial origin who are at present in subordinate ranks of the Colonial Service to qualify for promotion, particularly in branches where knowledge of medicine or biological subjects is required.

Scholarships in Aid of Scientific Research

The council of the British Medical Association is prepared to receive applications for the following research scholarships: an Ernest Hart memorial scholarship (£200), a Walter Dixon scholarship (£200), and four research scholarships (each £150). The scholarships are open to men or women undertaking research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given to members of the medical profession. Each scholarship is tenable for nine months from Feb. 1, 1947, and a scholar may be reappointed for not more than two additional terms. He may also hold a junior appointment at a university, medical school, or hospital provided the duties do not interfere with his work as a scholar. Applications must be made not later than Dec. 28, on a prescribed form, to be obtained from the secretary of the association, B.M.A. House, Tavistock Square, W.C.1.

Joint Tuberculosis Council

At the last meeting this council adopted a report suggesting the abolition of the present system of recording cases of tuberculosis, and proposing new definitions of such words as "quiescent" and "arrested." This report will not be published until the Ministry of Health has had an opportunity to consider it. Attention was drawn to the ruling that where family allowances are received by persons entitled to financial assistance under memorandum 266/T, the 266/T allowances must be reduced by the amount of family allowance received; and the council authorised a deputation to express to the Ministry the strong view that family allowances should have no effect upon allowances granted to tuberculous persons as such. Arising out of resolutions adopted at a previous meeting expressing alarm at the probable effect of the National Health Service Bill on the tuberculosis service, it was reported that a deputation representing the Joint Tuberculosis Council and the National Association for the Prevention of Tuberculosis had met Sir Wilson Jameson, who said that there was no intention to detach preventive work from curative work, and also gave assurances on other points. The council set up a special committee to consider the establishment of a Bureau of Tuberculosis Statistics, and decided to approach the Nuffield Foundation for assistance in the project.

B.A.L. as Antidote to Mercury

According to the British United Press, a two-year-ol in Los Angeles who swallowed three tablets of bichlor mercury has recovered completely owing to the admi tion of British anti-lewisite.

More Potent Penicillin

An American company, the Heyden Chemical Corpor is now producing white crystalline penicillin which, it i can be stored dry for three years without refriger According to a B.U.P. report, the potency of this prod the greatest yet developed commercially.

The Pharmaceutical Society has decided to ask the Mi of Supply to release to the public stocks of quinine whicl been held in chemists' shops during the war.

Appointments

BANNISTER, F. B., M.D. Lpool, D.A.: anæsthetist, Chester Infirmary.

COLBECK, J. C., M.B. Lond.: E.M.S. area pathologist, West F

HAINES, R. M., M.D. Lond.: director of pathology, Chelsea Ho for Women.

MILLIN, T. J., M.B. Dubl., F.R.C.S.: genito-urinary surgeon, C Hospital for Women.

PABLOT, P. J., M.B. Lond.: medical officer, Colonial Se Mauritius.

RAFTERY, L. M. N., M.R.C.S., M.R.C.O.G., M.M.S.A.: visiting cologist, British Red Cross Society's clinic for rheum London.

SHANNON, J. W., M.B. Lond.: medical officer, Colonial Se Nyasaland.

Diary of the Week

NOV. 17 TO 23

Monday, 18th

HUNTERIAN SOCIETY
8.30 P.M. (Apothecaries' Hall, Black Friars Lane, E.C.4) Hugh Linstead, Dr. G. H. Day, Mr. Arthur Mort Mr. J. S. Walmsley: That the Advertisement of prietary Medicines is a Menace to the Public.

Tuesday, 19th

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.1
5 P.M. Dr. J. Calvert Spence: Care of Children in Ho (Charles West lecture.)

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. J. T. Chesterman: Specimens Illustrating Inte Obstruction. (Erasmus Wilson Demonstration.)

ROYAL SOCIETY OF MEDICINE
4.30 P.M. *Pathology.* (Westminster Hospital School of Med S.W.1.) Demonstrations.

EUGENICS SOCIETY
5.30 P.M. (Burlington House, Piccadilly, W.1.) Prof. Kemp (Copenhagen): Fifteen Years' Experienc Negative Eugenics in Denmark.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. W. N. Goldsmith: Acneiform Eruptions.

Wednesday, 20th

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8.30 P.M. *Proctology.* Mr. A. Hedley Whyte: Proctol Past and Present. (Presidential address.)

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Po Place, W.1
3.30 P.M. Mr. C. W. A. Kimbell: Medical Aspects of Life Prisoner-of-war Camp.

Thursday, 21st

ROYAL COLLEGE OF SURGEONS
5 P.M. Mr. V. Zachary Cope: Actinomycosis. (Erasmus demonstration.)

ROYAL SOCIETY OF MEDICINE
5 P.M. *Dermatology.* Cases will be shown at 4 P.M.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE
8 P.M. (London School of Hygiene and Tropical Medicine, Street, W.C.1.) Laboratory meeting.

Friday, 22nd

ROYAL SOCIETY OF MEDICINE
2.30 P.M. *Epidemiology and State Medicine.* Dr. Robert C shank, Dr. O. H. Lidwell, Mr. F. Courtney Har Dr. Joyce Wright: Modern Methods in the Cont Airborne Infections.
5 P.M. *Pædiatrics.* Cases will be shown at 4.15 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street
9 P.M. Mr. H. Osmond Clarke: R.A.F. Experiences of the M Treatment of Fractures. A film will be shown.

GENETICAL SOCIETY
5 P.M. (London School of Hygiene and Tropical Medicine.) Tage Kemp: Multiple Factors in Morbid Inheri Film: Fat Dwarf.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, W.C.1
4.30 P.M. Dr. P. A. Owren (Oslo): New Factors Concer the Coagulation of Blood.

LONDON CHEST HOSPITAL, Victoria Park, E.2
5 P.M. Mr. T. Holmes Sellors: Surgery of the Heart.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY
8.30 P.M. Dr. Macdonald Critchley: Sir William Gowe Biographical Study.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh
8 P.M. Dr. J. McMichael: Heart Failure.

ABSORPTION AND EXCRETION OF WATER

THE ANTIDIURETIC HORMONE*

E. B. VERNEY
M.A., M.B. Camb., F.R.C.P., F.R.S.
SHEILD PROFESSOR OF PHARMACOLOGY IN THE UNIVERSITY OF CAMBRIDGE

Oliver and Schäfer (1895) showed, in the anæsthetised dog, that the intravenous injection of extracts of whole pituitary gland raised the arterial pressure, the rise being of peripheral origin and lasting far longer than that after injections of extracts of the suprarenal medulla. Howell (1898) demonstrated that the pressor activity of extracts of the pituitary was derived solely from the posterior lobe, a fact confirmed by Schäfer and Vincent (1899). Schäfer and Magnus (1901) discovered that intravenous injection of extracts of the infundibular portion of the hypophysis into the anæsthetised dog produced "after a short latent period a remarkable and long-continued expansion of the kidney accompanied by a decided and often prolonged diuresis." Schäfer and Herring (1906) showed that the diuresis was essentially independent of the vascular change in the kidney, and that very often the diuresis was preceded by an inhibition of urine flow, even though the vascular conditions were throughout favourable to free secretion. Schäfer clearly recognised at this early date both the diuretic and the antidiuretic activities of postpituitary extract, and he postulated their inherence in two discrete substances.

Schäfer (1909) subjected the pituitaries of three dogs to mechanical injury or to partial destruction with a feeble thermocautery and found that in all a polyuria supervened during the 4–11 postoperative days over which the observations were made. These results gave the first clear indication of functional linkage between the kidney and the pituitary.

The clinical counterpart of these last experiments by Schäfer was revealed in Frank's (1912) observation of the frequent association of diabetes insipidus with injuries to the hypophysis; and, following Schäfer's interpretation of the results of his experiments on the dog, Frank expressed the view that diabetes insipidus in man was attributable to pathological overactivity of the pars intermedia. Von den Velden (1913) and Farini (1913), however, demonstrated the efficacy of injections of postpituitary extract in relieving the signs and symptoms of the human disease, and Von den Velden was clearly puzzled by the conflict between his results and the current interpretation of Schäfer's experimental findings. Since that time evidence has been gradually accumulating that the polyuria frequently observed to be associated with experimental or pathological lesions of the pituitary and hypothalamus is to be ascribed rather to lack of the postpituitary antidiuretic substance than to liberation or increased secretion of Schäfer and Magnus's diuretic substance, evidence which has culminated in the elegant demonstration by Ranson et al. (1938) that in the cat and the monkey diabetes insipidus is contingent on the complete degeneration or removal of the neurohypophysis.

There are two other conditions under which a profuse watery diuresis is observed: the perfusion of the dog's kidney in the isolated state (Verney and Starling 1922, Starling and Verney 1925), and the ingestion of a large volume of water by the normal mammal. The diuresis seen in the perfused isolated kidney is specifically inhibited by the addition of postpituitary extract to the perfusing blood, the fall in the output of water being accompanied by an increase both in the concentration of chloride in the urine and in the rate of chloride excretion. These effects of postpituitary extract are closely simulated by switching the head of a dog into perfusion-parallel with the kidney, the inhibition of diuresis and increased excretion of chloride then depending on the presence of the pituitary in the perfused head (Verney 1926). There can be little doubt about the substantial correctness of the view put forward at the time, that the profuse watery diuresis exhibited by the perfused isolated kidney is due to the divorce of the kidney from the inhibitory influence of the postpituitary antidiuretic substance and has essentially the same ætiology as diabetes insipidus.

But it is particularly with the profuse watery diuresis following water ingestion that I wish to deal here. The importance of the experimental investigation of the processes underlying this phenomenon resides in the possibility of determining whether the postpituitary antidiuretic substance is a hormone in the full physiological sense—i.e., whether its secretion is continually varying according to the contemporary osmotic pressure of the arterial plasma and being as continually and reversibly engaged in determining the rates of water and chloride excretion by the kidney.

LAG BETWEEN ABSORPTION AND EXCRETION OF INGESTED WATER

The response of the kidney to the ingestion of water can be accurately measured in bitches in which, by an earlier aseptic operation, the ureters have been extended to the exterior. When to such an animal, weighing about 10 kg., 250 c.cm. of water is given by stomach-tube, the resulting diuresis reaches a peak about 50 min. later. By the repetition of these observations on several animals a curve representing the group mean of the individual mean rates of secretion of urine is obtained, and the peak of this mean in experiments conducted by Klisiecki et al. (1933) lay accurately at 50 min. after the administration of the water (fig. 1).

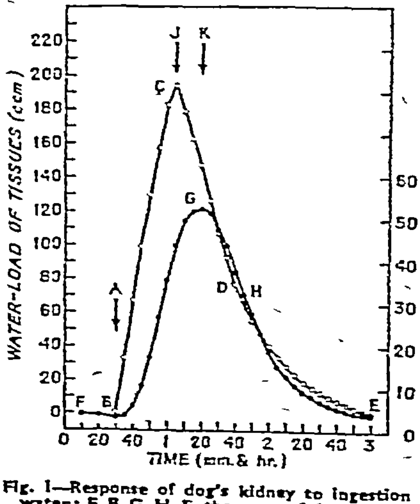

Fig. 1—Response of dog's kidney to ingestion of water: F, B, G, H, E, the mean of the mean rates of secretion in 9 dogs; B, C, D, E, water-load curve; A, time of giving water. (Klisiecki et al. 1933.)

The rate of absorption of water from the gut can be determined in the following way. When the excretion curves have been obtained, a further 250 c.cm. of water is given, and at a predetermined time after this the animal is rapidly rendered unconscious with chloroform and the heart immediately punctured through the chest wall: from the volume of water remaining in the gut the volume absorbed in the period between the giving of the water and the death of the animal becomes known. The results of ten such observations are shown in fig. 2, the time-element in each being taken as the interval between the mid-time of introduction of the water and the time of puncture of the heart. The absorption curve (fig. 2) reaches the 250 c.cm. level in 35½ min. Subtraction of the water-excretion curve (fig. 2) from the water-absorption curve gives the water-load curve (fig. 1), which represents the amount of water temporarily held in the tissues in excess of the optimal. The peak of the water-load curve precedes that of the mean rate of urinary secretion (fig. 1) by 15 min. If we regard the water-load curve as tracing the intensity of the stimulus to which the kidney eventually responds, we must conclude that there is a lag of 15 min. between the maximal intensity of stimulus and the maximal response by the kidney. The response by the denervated kidney runs exactly parallel with that of the innervated kidney. I shall consider later the significance of this 15-min. lag; in the meantime I wish to draw attention to the analysis of the inhibition produced by various agencies in the flow of urine during water diuresis, in particular to that of the inhibitory effect of (1) muscular exercise, (2) emotional stress, and (3) a rise in the osmotic pressure of the carotid arterial plasma.

---

* Abridgment of the sixth Sharpey Schafer memorial lecture, delivered in Edinburgh on June 8, 1945.

INHIBITORY EFFECT OF MUSCULAR EXERCISE ON WATER DIURESIS

To ensure that the flow of urine from the urethra is accurately conforming with contemporary secretion by the kidney, it has been found desirable, in many of these investigations, to reduce the urinary conducting tract so far as possible to simple tubular form by excising the fundus of the bladder, thus eliminating any irregularities occasioned in the recorded flow by contraction and relaxation of the bladder's musculature.

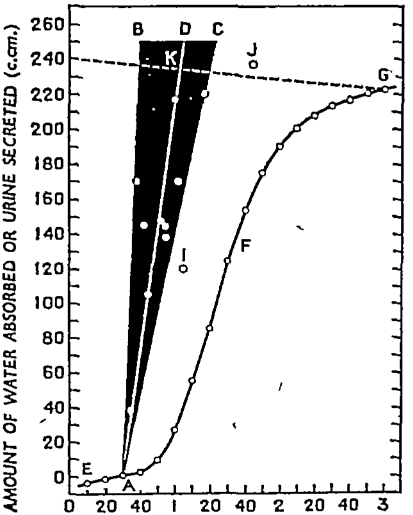

Fig. 2—Response of dog's kidney to ingestion of water: E, A, F, G, mean excretion curve, water having been given at A; white points represent volume of water absorbed from gut in allotted time; AKD, mean absorption curve (mean of lines from A through each white point). (Klisiecki et al. 1933.)

The operative procedure consists, in brief, in exposing and opening the bladder, passing down the urethra a short length of rubber catheter-tubing tied above to a short funnel-shaped glass cannula, adjusting the cannula so that its upper lip is immediately below the ureteric openings, and fixing it in this position with a ligature which encircles the urethra at the level of the sphincter of the trigone; the fundus of the bladder is then removed and the remnant closed with a single row of fine silk sutures. So far as Rydin and Verney (1938) were able to judge, such animals maintain health indefinitely; accuracy in following the rate of urine secretion is thus not made contingent on a shortening of the animal's period of survival.

It now became necessary to subject such animals to short periods of exercise and to measure continuously the effects of this procedure on water diuresis. For this purpose a moving platform was designed, the speed of which could be measured and suitably varied, the dog being tethered to the superstructure during the whole course of the urine-flow measurements.

We found that mild exercise—e.g., running at 6 m.p.h. for 4 min.—was usually followed by a well-marked and protracted inhibition of urine flow (fig. 3). During the first 2 min. of the period of exercise no fall in the rate of urine flow was observed; indeed, there was sometimes a small increase, and only during the second 2-min. period did a decrease begin, the rate falling progressively towards its lowest value. The cessation of exercise was apparently without influence on the course of the decline, and the degree and extent of the inhibition varied widely in different animals in response to running at the same speed and over the same period. The longer inhibitions were always accompanied by an increase in the percentage of chloride and of nitrogen in the urine and by a contemporary increase in urinary pigment. The variability in the inhibitory responses to a constant amount of exercise, their apparent relation in any one animal to an emotional accompaniment, and their inception by events taking place early in the period of exercise made it desirable to divorce any contribution which short exercise might make to the inhibitory effect from that due to an associated emotion. We were able to do this in three ways.

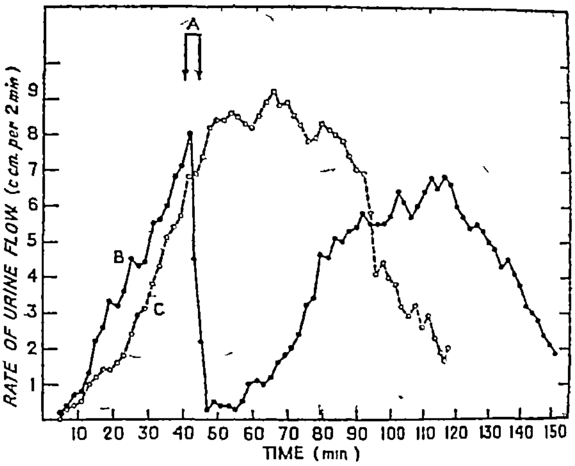

Fig. 3—Water-diuresis curves from a bitch, in which fundus of bladd was excised and urethral cannula implanted 10 days before, and 25 c.cm. of water given at zero time: B, response on August 7, 1935; C response on August 8 (response on August 6 was closely parallel wit C); *A, period of exercise, running at 6 m.p.h., during response B.* I this and all similar figures, the rate of urine flow is plotted in the *middl* of the period to which it refers. (Rydin and Verney 1938.)

EFFECT OF EMOTIONAL STRESS

First, it was easy to show that, if the animals were repeatedly exercised, the inhibitory response progressively diminished to final extinction. Muscular exercise, therefore, is not *per se* causally related to the inhibitory response; and the view that psychological factors are essentially involved is supported by the observation that inhibition has been noted on occasions when an animal resented undertaking the very exercise which had previously not elicited a response.

Secondly, if the exercise, the response to which had been extinguished by repetition, was combined with an

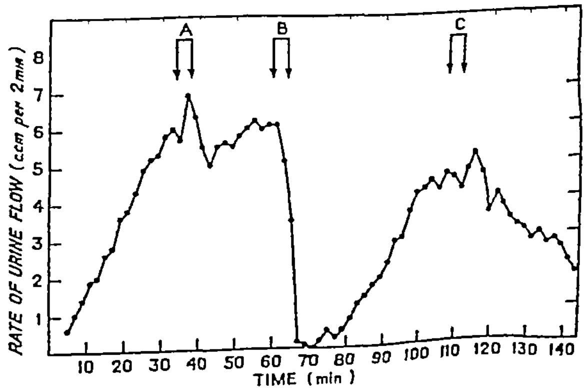

Fig. 4—Water-diuresis curve from bitch to which 250 c.cm. of water was given at zero time. During periods A and C the bitch ran on the platform quite happily. During B the same exercise was given and the bitch frightened by the repeated soundings of a car-horn. (Rydin and Verney 1938.)

unfamiliar and ugly sound, the inhibitory response reappeared. In the experiment charted in fig. 4 the animal was subjected to three similar periods of familiar exercise (A, B, and C); but, whereas during A and C the exercise was simple, during B it was combined with the repeated sounding of a car-horn, to which the animal exhibited fright. There can be no question, therefore, that the inhibitory response which began during B was due not to the exercise but to its emotional accompaniment.

We were thus led, in the third place, to measure the effect of emotional stress alone. For this purpose a weak faradic current was carried to the subcutaneous tissues by surgically clean needle electrodes, and its rength was increased until the animal showed signs resentment. Such a stimulus produced inhibitory sponses indistinguishable from those already described. nd in later experiments this simpler and more con-ollable form of stimulus has usually been used for the nalysis of the resultant inhibition.

How, then, does emotional stress produce this nhibition? The first suggestion is that the inhibition of vasomotor origin, with consequent constriction f the vasa afferentia and a fall in the glomerular capillary ressure, though the rise in the chloride concentration of he urine during the inhibition argues against such inter-retation. The suggestion is, however, disproved by the fact that after denervation of the kidneys the form of the inhibitory response is apparently unaltered. There is a rise in arterial pressure during the emotional stress: hence in the absence of any change in the composition of the blood it is reasonable to infer that, after denervation of the kidneys, at least no fall in glomerular capillary pressure results from the stress.

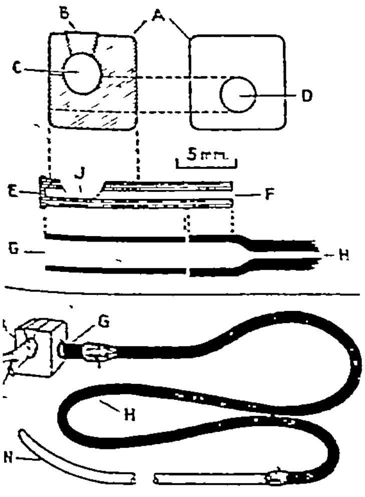

Fig. 6—Compression unit for renal artery. In the upper part are shown the component parts of the unit; in the lower part, and on a smaller scale, the parts assembled: A, bakelite cube; B, wedge; C, channel for renal artery; D, channel for silver tube E-F; J, sector removed from silver tube; G, thin rubber tube; H, pressure-tube extension of E-F. To assemble these parts the thin rubber sleeve G is slipped over E-F into the position indicated, and the unit so formed is then passed through the channel D. Into this it fits tightly, and the circumference of the opening J corresponds in position to, and slightly outruns, that of the arterial channel C in its lower part. Round the sleeve G are tied two ligatures, one on either side of the bakelite cube, and the lumen F is filled completely with 0·9% NaCl. The pressure-tube extension H, already filled with saline, is now slipped over the open end of the silver tube and tied there securely. A fine needle is then pushed into the lumen of H near its lower end and a little fluid withdrawn with a syringe. The sleeve G thereby collapses into the sector J and frees completely the arterial channel C. N, thin steel rod; L, renal artery with its two primary branches. Before use the unit is tested and calibrated by determining the volume of fluid which it is necessary to inject into it to stop the flow of water perfused under a pressure of 140 mm. Hg through a length of rubber tubing temporarily resting in the arterial channel C. We have used two sizes of unit, the diameter of C being 3·5 mm. in the one and 4·0 mm. in the other. (Rydin and Verney 1938.)

But, it will be said, adrenaline was released during the period of stimulus, and this adrenaline, especially after division of the renal nerves, led to vasoconstriction in the kidney. This perfectly valid criticism collapses when put to the test of experiment. In fig. 5 are given two responses to emotional stress in one animal. A month after the kidneys had been denervated the response B was obtained. Next day the right suprarenal was removed and the left denervated. Five days later the response C was obtained. There is no essential difference between the forms of the two responses, and during the following 16 days seven other responses of similar type were obtained. If, then, we assume that the liberation, by emotional stress, of adrenaline from the suprarenals is mediated only by the gland's nerve-supply, and that no other agent is liberated in effective vasoconstrictor amount, we are led by these results to infer that the inhibitory response observed in the normal animal is conditioned neither by the secretion of adrenaline nor by a fall in the rate of renal blood-flow.

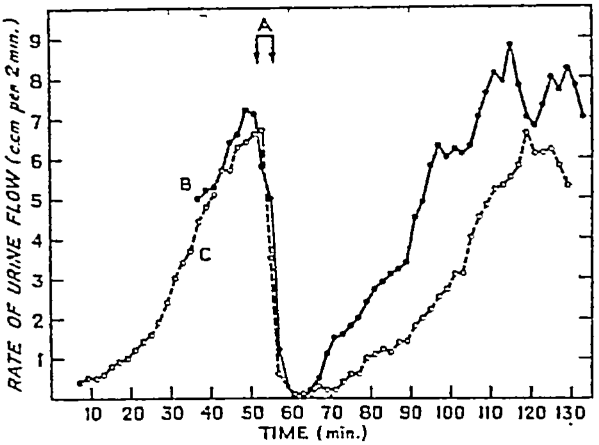

Fig. 5—Water-diuresis curves from bitch (kidneys denervated) to which 250 c.cm. of water was given at zero time in curve C, and at 31 min. in curve B. During period A the animal ran on the platform and was angered by noise. Curve B was obtained 1 day before, C 5 days after, the right suprarenal gland had been removed and the left denervated. (Rydin and Verney 1938.)

Dissimilarity to the Inhibition Produced by Temporary Compression of the Renal Artery.—The possibility of there being a causal relationship between changes in renal blood-flow and the inhibition of urine flow by emotional stress has also been questioned in another way.

A small compression unit was designed (fig. 6) which could be implanted by aseptic operation at the origin of the right renal artery, the left kidney being removed at the same time, and could temporarily arrest the renal blood-supply later without the animal being aware of the fact. The effect of this procedure on the course of water diuresis was determined. The implanted unit becomes snugly ensheathed in a thin capsule of fibrous tissue, and its presence is without apparent influence on either the animal's normal health or its survival period.

Fig. 7 shows the effects of $2\frac{1}{2}$ and 3 min. periods of occlusion of the renal artery. On release of the compression the urine flow suddenly mounts to at least its

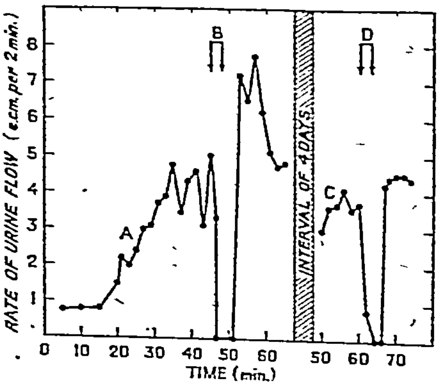

Fig. 7—Effects of temporary compression of renal artery on water diuresis in normal dog. Each rate of urine flow is plotted at the end of the period to which it refers. In each experiment 300 c.cm. of water was given by stomach-tube at zero time, a preliminary hydrating dose of 250 c.cm. having been given 4 hours previously in the first experiment and $2\frac{3}{4}$ hours previously in the second. B, D, periods of compression of renal artery. (Rydin and Verney 1938.)

rate before the artery was occluded; this takes place irrespective of whether the inhibition of urine flow is complete from severe compression or partial from moderate compression of the renal artery. The character of the response thus becomes sharply differentiated from that resulting from emotional stress and supports the evidence already adduced for the view that the response to emotional stress is not determined by hæmodynamic factors.

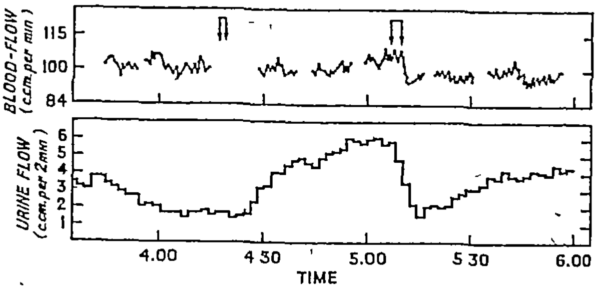

Fig. 8—Blood-flow and urine flow through denervated kidney in a dog subjected to emotional stress. Between the first pair of arrows 250 c.cm. of water was given by stomach-tube; between the second pair the animal was annoyed by mild faradic stimulation. (Cowan, Verney, and Vogt, unpublished observations.)

Measurement of Renal Blood-flow during Emotional Stress.—Some years ago Dr. S. L. Cowan, Dr. M. Vogt, and I decided to attempt the direct measurement of the blood-flow through the kidney during the inhibition from emotional stress, and the results demonstrated the essential correctness of the inference drawn by Rydin and myself from evidence of an indirect nature. The results have not yet been published, but Dr. Cowan and Dr. Vogt have very kindly allowed me to present the essential features † of the work which we did together.

We have used Rein's (1928, 1929a and b, 1931) thermostromuhr method, the thermostromuhr unit being a modification of that designed by him. It is made from a bakelite block and is a little longer than Rein's, so that the thermocouples are further from the ends, and the risks of small displacements of the unit and consequent variations of thermal contact with a wall of a blood-vessel are reduced. The heating and galvanometer leads are enclosed in very fine rubber tubes, and the whole unit can be sterilised by boiling. An approximate calibration of the instrument was made before use by placing a strip of artery inside it and perfusing this with defibrinated blood; and an accurate calibration curve was obtained, after the animal had been killed, by perfusing the renal artery in situ, a calibration which was facilitated by the addition of a little chloral to the blood to inhibit spontaneous contractions of the artery (Petersen 1936).

In the preparatory operation one kidney is removed and the stromuhr is slipped on the renal artery of the other close to its origin. The galvanometer leads are passed down one uterine horn, the heating leads down the other, and thence they pass through the uterus to the vagina, where they remain accessible for the purpose of future blood-flow measuremen The fundus of the bladder is excised and a self-retainin catheter left in the residual stump. The abdomen is th closed. Recovery is rapid and uneventful, and all ou observations have been made on animals in a state of excelle health.

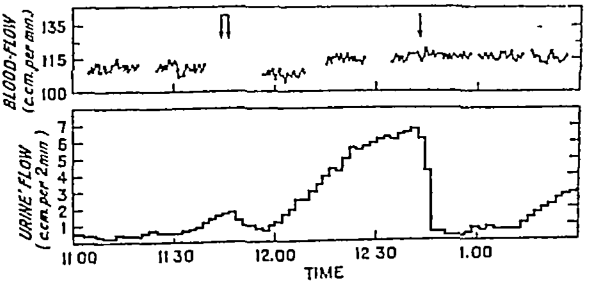

Fig. 9—Further observations on the animal from which the results in fig. 8 were obtained. Between the first two arrows 350 c.cm. of water was given by stomach-tube. At the third arrow 4 mU of postpituitary extract was given intravenously. (Cowan, Verney, and Vogt, unpublished observations.)

Fig. 8 shows the course of the renal blood-flow durin an experiment in which an inhibition of water diuresi was produced by emotional stress. In this animal th stromuhr had been implanted on the right renal artery the right suprarenal and the left kidney had been remove and the left splanchnic nerves divided at the sam operation. There is a small fall in blood-flow, and i was found that this small fall might outlast the retur of diuresis, but the fall was usually less than the change in flow developing spontaneously in the course of a experiment. Such changes were of the order of 10 and were encountered even when the animal was standin still; they were unaffected by the giving of water b mouth or by small doses of postpituitary extract intra venously (fig. 9). An intravenous injection of adrenalin 10 μg., on the other hand, produced a well-marked bu transitory fall in blood-flow.

In connexion with this work two points must b emphasised. (1) By 4–5 days after the operation th unit had become snugly ensheathed in a thin fibrou capsule, which immobilised it on the arterial wall an so minimised any changes in galvanometer deflectio from variations in thermal contact between the thermo couples and the arterial wall. The unit remained s protected and immobilised during the final calibration which was carried out immediately after the animal ha been killed. (2) The health of the animals on which ou observations were made was in every respect excellent These results, then, afford direct evidence for the view that the inhibition of water diuresis by emotional stres is independent of changes in renal blood-flow, the small changes observed being incidental rather than causal.

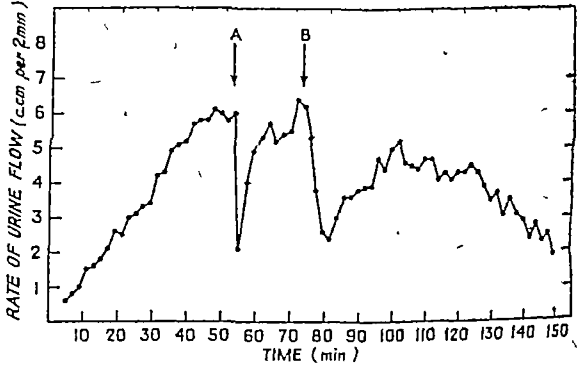

Fig. 10—Water-diuresis curve from bitch in which both kidneys had bee denervated 16 days before and 250 c.cm. of water given at zero tim At A, 1 c.cm. of 0·9% NaCl containing 0·02 mg. of adrenaline HCl and at B, 1 c.cm. of 0·9% NaCl containing 10^{-3} c.cm. of standardise postpituitary extract (10 U/c.cm.) was injected intravenously. (Rydi and Verney 1938.)

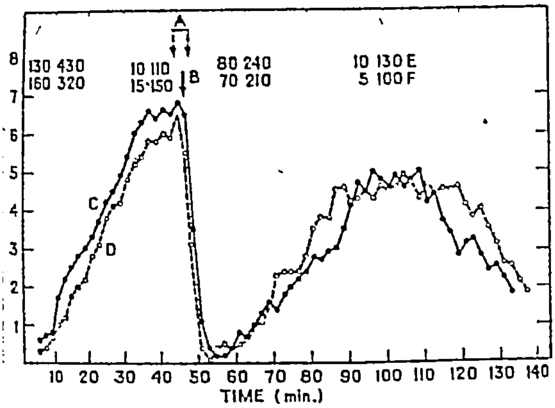
Comparison of Inhibitory Response to Emotional Stres with that to Intravenous Injection of Adrenaline and o Pituitary (Posterior Lobe) Extract.—These facts having been established, it became of interest to compare the inhibitory effect of transient emotional stress with that of the intravenous administration of the two endogenous agents, adrenaline and postpituitary extract. Curves typical of the effects of these two drugs are shown in fig. 10, and the forms of response remain true to type in whichever order they are elicited on the plateau of diuresis. The response to adrenaline, by its sudden fall and almost equally sudden recovery, is quite unlike that to emotional stress. When, however, the response to emotional stress is compared with that to postpituitary extract, so close a correspondence is obtained

---

† These were communicated to the Physiological Society on March 12, 1938.



11—Water-diuresis curves from bitch, curve C being obtained on lov. 21, curve D on Nov. 25, 1935. The kidneys had been denervated n Oct. 14; right suprarenal gland removed and left denervated on lov. 15. At B, during the course of C, 5 × 10⁻⁴ c.cm. of postpituitary xtract (10 U/c.cm.) was injected intravenously. At A, during the ourse of D, the animal was angered by noise. E, chloride (as NaCl) in mg./100 c.cm. urine, and nitrogen in mg./100 c.cm. urine, at four periods during the course of experiment C; F, corresponding figures during the course of experiment D. (Rydin and Verney 1938.)

th in the courses of urinary water and in those of urinary loride and nitrogen as to encourage the belief that the o phenomena have the same immediate cause. Indeed, th a suitable dose of postpituitary extract the two sponses are indistinguishable (fig. 11), and with each ere is a latent period of some 2 min. before the inhibitory sponse begins. Such a dose of postpituitary extract ves the arterial pressure unaffected, and the absence change in renal blood-flow (fig. 9) gives to this agent an ditional qualification for identity with that responsible r the inhibition from emotional stress.

But a resembling relationship between phenomena es not carry the conviction of causal identity, and it came imperative to obtain direct evidence on the estion of such identity by measuring the response emotional stress before and after removal of the sterior lobe of the pituitary. This has been attempted O'Connor and Verney (1942), and we have used chner's (1912) original method of approach to the tuitary through the basisphenoid.

Effect of Removal of Posterior Lobe of Pituitary on hibition of Water Diuresis by Emotional Stress.—he results we obtained were unequivocal, in that the sponse to emotional stress after removal of the posterior be of the pituitary was very much reduced when mpared with that before removal. Assay, in terms postpituitary extract, of the responses before and after moval of the posterior lobe showed that only about 5% of the antidiuretic function of the neurohypophysis, as expressed in the inhibition by emotional stress, remained when the posterior lobe had been removed. Before removal of the posterior lobe the response to the stimulus was closely matched by that to 5 mU of postpituitary extract injected intravenously (fig. 12), and a month after removal of the posterior lobe the response to the same stimulus had a value of about 0·1 mU (fig. 13), the average postpituitary equivalent of ten such tests being 0 2 mU.

In these experiments removal of the posterior lobe was followed by an increase in the daily output of urine from a preoperative value of about $^1/_4$ litre to a value of 1–2 litres for the first 2–4 days. The increase then gradually subsided, and the output of urine was apparently normal from about a week after the operation. Polyuria following operative interference with the pituitary was reported as an occasional manifestation by Vassale and Sacchi (1892) and Gemelli (1908), but Schafer (1909) first linked its appearance with the actions of posterior-lobe extract on the kidney. More recently the temporary polyuria has been observed by Fisher et al. (1938) working on the cat and by Pickford (1939) working on the dog. As much as 95% of the antidiuretic activity of the neurohypophysis, as assessed in the emotional inhibition of water diuresis, can be abolished without producing such an impairment in the animal's ability to conserve its tissue water as would be expressed in a permanent increase in urine flow.

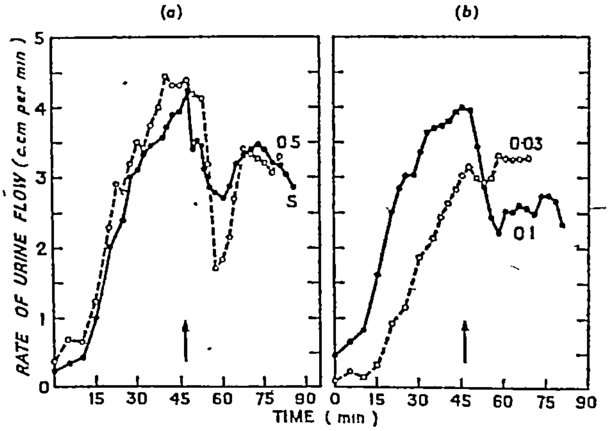


Fig. 13—Estimation of amount of antidiuretic substance liberated in response to 40 sec. emotional stimulus of same strength in same bitch as in fig. 12 but 1 month after removal of the posterior lobe: (a) inhibition resulting from emotional stimulus compared with that from 0 5 mU injected during the curve of the previous day; (b) inhibitions from 0 1 mU on the day after the curves of (a) and from 0·03 mU on the day before the curves of (a). (O'Connor and Verney 1942.)

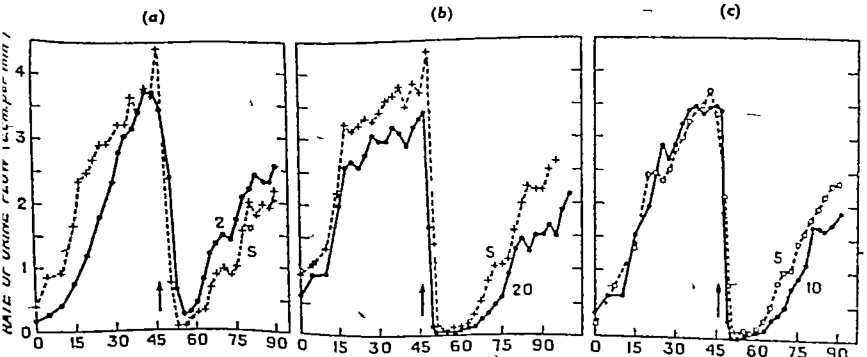
Probable Pathway through which Emotional Stress Operates.—A study of the inhibition of water diuresis by emotional stress has, then, led to the demonstration of the release of antidiuretic substance from the posterior lobe of the pituitary when a suitable stimulus is given to the normal animal. Now, Pickford (1939) has shown that, in the atropinised dog, acetylcholine produces a temporary inhibition of water diuresis, an inhibition which no longer develops after removal of the posterior lobe. The percentage of chloride in



ig. 12—Estimation of amount of antidiuretic substance liberated in response to 40 sec. emotional stimulus before removal of posterior lobe in bitch weighing 11 2 kg. Dose of water=300 c.cm. Stimulus and injection were given at the arrow: (a) inhibition produced by emotional stress (graph S) is compared with that resulting from intravenous injection of 2 mU (graph 2); (b) another inhibition from an equal stimulus (graph S) is compared with that from 20 mU (graph 20); (c) inhibitions resulting from 5 and 10 mU. (O'Connor and Verney 1942.)

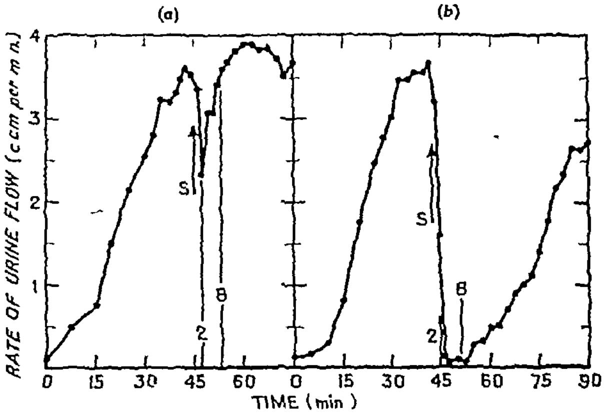


Fig. 14—Water-diuresis curves of dog weighing 10 kg.: (a) August 21, 1942, *before operation; S, 60-sec. faradic stimulation.* Oct. 28, 1942, *denervation of the kidneys* and *suprarenals.* (*b*) Nov. 24, 1942; S, 60-sec. *faradic stimulation.* (O'Connor and Verney 1945.)

the urine and the rate of chloride excretion rise during the period of inhibition of the diuresis; and there can be little doubt that the acetylcholine is producing these changes in the excretion of water and chloride by stimulating directly or indirectly the hypothalamic neurones whose axons pass down the stalk to the posterior lobe and by whose activity the pituitary antidiuretic substance is released. Equally, there can be little doubt that emotional stress produces such release by similar involvement of the hypothalamic nuclei.

Effect of Increased Activity of Sympathetic System on Inhibition.—Before leaving the subject of the inhibition of water diuresis by emotional stress, I wish to refer briefly to the relation of increased activity of the sympathetic system with this inhibition. O'Connor and Verney (1945) have found that with many dogs the response to emotional stress during water diuresis is a sharp short inhibition, that this rapid inhibition is abolished by section of the splanchnic nerves and denervation of the kidneys and suprarenals, and that then the long slow inhibition of pituitary origin invariably appears. Fig. 14 shows the rapid response of sympathetic origin, and the slow response of pituitary origin which appeared after section of the splanchnics and denervation of the kidneys and suprarenals. The slow inhibition thus revealed could be prevented by the injection of adrenaline just before the application of the faradic stimulus.

There are two possible explanations of this: either the adrenaline is interfering with the action of released pituitary antidiuretic substance on the kidney, or it is preventing the release of this substance. That the latter is the correct interpretation was shown by the fact that adrenaline did not diminish the inhibition produced by postpituitary extract. Moreover, if the adrenaline is injected 30 sec. after instead of 30 sec. before the faradic stimulus, the full inhibition of pituitary origin appears. The irregular appearance of the slow inhibition in normal dogs is thus explicable in terms of non-release of antidiuretic substance from the posterior lobe owing to increased sympathetic activity during emotional stress. The action of adrenaline in this regard is not specific, since tyramine in equipressor doses is just as effective, and it seems probable that an increased cerebral blood-flow is the common factor in preventing the release of antidiuretic substance.

Now, Rydin and Verney (1938) had observed that an inhibition of the pituitary type followed the removal of small volumes of arterial blood from animals subjected to section of the splanchnics or to a combination of this with abdominal sympathectomy, conditions which we now see to be peculiarly favourable to the release of antidiuretic substance by emotional stress. May it not be that in states of low sympathetic tone in man, associated perhaps with pathic stimuli and with hæmorrhage, the conditions are equally favourable to the pr secretion of antidiuretic substance by the pi If that is so, the beauty of the fitness of distantly eve *processes for recruitment to the current accidental* for the conservation of such water as is in excess of required for essential excretory work by the ki *becomes immediately manifest.*

The demonstration, in the normal animal, of release of pituitary antidiuretic substance by the arti *means of faradic stimulation of sensory nerves* receptors, and the fact that this release may be ca by such mild disturbance of the central nervous system comes within a physiological range—even the anticipati *of a nocuous stimulus which the animal has previous* experienced may be effective—encouraged an attem to determine whether the secretion of this substance w not continuously varying with, and under the dir control of, some factor in the animal's internal enviro ment, to the maintenance of which factor within a narro physiological range the renal secretion of water and chloride would specifically contribute.

(*To be concluded*)

LUNG LESIONS IN SKELETAL TUBERCULOSIS

REVIEW OF 500 CASES

K. J. MANN
M.D. Lond., M.R.C.P., D.T.M. & H.
PHYSICIAN E.M.S.

THE association of bone and joint tuberculosis w pulmonary lesions of the same ætiology has been rec nised for many centuries, but reliable data were available until the last few decades, with the adva in the pathology and radiological interpretations tuberculous lesions. Papers by different authors ha been published, all of which prove the intimate relati between pulmonary and extrapulmonary tuberculosis.

The present series comprises 500 cases of skele tuberculosis in patients admitted to the Royal Natio Orthopædic Hospital, Stanmore, during the last th years. These patients, generally resident in Lon and the home counties, were admitted irrespective the severity of the skeletal lesion, provided they w *known to have no open pulmonary tuberculosis.* It therefore a selected series of patients without tube bacilli in their sputum, but with recent development skeletal tuberculosis. No old cases or readmissions w included.

The diagnosis of the tuberculous nature of the bone joint lesion was made by the orthopædic surgeons charge of the cases on typical clinical *and* radiologi findings, by isolation of the tubercle bacillus from or granulation tissue, and by biopsy of tissue remo from the diseased part or its draining lymph-glands. A case where *the* tuberculous nature *of* the lesion was doubt was excluded.

Once the diagnosis of the skeletal lesion was ma each case was submitted to an investigation of respiratory system. This included history of past present symptoms referable to the chest, *present sign* the chest, radiological investigations, sputum examinat when available, and sedimentation-rate. In some ca gastric lavage and guineapig inoculation were *also* do All the cases were reviewed, clinically and radiologica at three-monthly *intervals. A post-mortem* examinat was carried out on 4 out of 8 patients, who died while hospital, to confirm the clinical findings in the respirato system.

FINDINGS

Of the 500 cases, 287 were *males* and 213 femal They were subdivided, irrespective of sex, into five-ye oups up to puberty; adolescence and early working e were taken together (15–24); the remainder were vided arbitrarily into those below and those above 40.

Age-group (yr.)		*Males*		*Females*		*Total*
0– 4	..	39	..	26	..	65
5– 9	..	47	..	29	..	76
10–14	..	36	..	20	..	56
15–24	..	77	..	69	..	146
25–39	..	64	..	49	..	113
40 plus	..	24	..	20	..	44
Total	..	287	..	213	..	500

To give a more complete picture of the material under onsideration, the tuberculous skeletal lesions from which hese patients were suffering are analysed in table I. he number of patients is smaller than the number of sions because of multiple lesions in the same patient.

Past Symptoms Referable to Respiratory System.—Of hese the only two to which clinical significance could be ttached were the history of past sanatorium treatment and that of an acute attack of pleurisy.

Past sanatorium treatment for pulmonary lesions was underone by 26 patients, 5% of the total number. In some cases he skeletal lesion developed as late as twenty years after the ulmonary lesion. In others it preceded the latter by 1–3 ears. The majority, however, came on within three years of ischarge from the sanatorium. Only 4 received collapse herapy, 3 thoracoplasty, and 1 A.P. Of the 26 patients who eceived sanatorium treatment, 12 had no active pulmonary sion clinically or radiologically when examined in the course f this investigation.

+	24	1	9	9	1	0	1	2	2
otal	206	28	126	85	26	9	5	10	24

Pleurisy.—43 patients had an attack of pleurisy which receded the skeletal lesion by an average of two years, the ngest interval being twenty years. In some cases it was elayed 1–6 years after the onset of the skeletal lesion. Of he total number, 4 were bilateral. 24 of the 43 cases still howed active pulmonary lesions when examined.

Present Symptoms Referable to Respiratory System.—In iew of the selected series of cases, such symptoms were eagre. Cough was present in 12%, expectoration in %, and hæmoptysis in 1%.

Physical signs in the chest were present in 12% of the atients and varied greatly in degree.

Sputum tests were positive in 6 patients, who were ransferred immediately to a sanatorium.

Gastric lavage and guineapig inoculation were carried ut in a small unselected series of cases. Of 64 tests, 18 ere positive. The number of tests and results according o age-groups were as follows:

Age-group (yr.)		*No. of tests*		*No. positive*
0– 4	..	13	..	3
5– 9	..	6	..	2
10–14	..	5	..	1
15–24	..	25	..	7
25–39	..	10	..	3
40 plus	..	5	..	2
Total	..	64	..	18

he organisms isolated from the sputum and gastric avage were in all cases of the human type.

Sedimentation-rate.—The extrapulmonary lesions were usually responsible for the high readings obtained. Occasionally one could attribute the high sedimentation-rate to the pulmonary lesion, but on the whole this objective test was of no value in determining the activity or otherwise of pulmonary shadows.

Radiological Investigation.—The history, symptoms, signs, and bacteriological investigation were of little assistance in determining the presence of early lung disease. It was necessary, therefore, to rely on the radiological appearances for the diagnosis of pulmonary lesions and their classification. Radiograms were taken on admission and repeated at three-monthly intervals. Where required, penetrating and lateral films were taken to assist in the evaluation of doubtful shadows in the A.P. films. In children a negative result of radiography of the chest was not taken as final. Radiography was repeated after an interval of 3–6 months, and in a few the primary lung infiltration, which was not visible in the first radiogram, became apparent in the later ones. In the same way progression of the disease in mediastinal glands produced in a few months mediastinal shadows easily identifiable as pathological on the later radiograms. Activity in patients with negative sputum and gastric lavage was judged partly by the appearance of the radiological shadows in the first radiogram and partly by the regression or progression of these shadows in later radiograms. Only cases fulfilling the above criteria were included among those taken as showing active pulmonary lesions. Calcified lesions were interpreted as normal.

TABLE II—DISTRIBUTION OF TUBERCULOUS LESIONS

Age-group	Primary complex			Hæmatogenous foci only	Bronchogenic tuberculosis	Normal
	Lung and glands	Glands only	+hæmatogenous foci			
0– 4	35 (*54%*)	16 (*25%*)	4 (*6%*)	0	0	10
5– 9	31 (*41%*)	22 (*29%*)	5 (*7%*)	4 (*5%*)	0	11
10–14	13 (*23%*)	12 (*21%*)	3 (*5%*)	2 (*4%*)	0	26
15–24	4 (*3%*)	3 (*2%*)	6 (*4%*)	58 (*40%*)	2 (*1%*)	73
25–39	1 (*1%*)	0	0	39 (*34%*)	7 (*6%*)	66
40 +	0	0	0	10 (*24%*)	7 (*16%*)	27
Total	84 (*17%*)	53 (*10%*)	18 (*4%*)	113 (*23%*)	16 (*3%*)	216

Of the 500 patients, 284 (57%) showed active intrathoracic lesions. The percentage of lung lesions in the younger age-groups is 84, diminishing to 40 in the older age-groups, as shown by the following analysis:

Age-group (yr.)		*Total*		*No. affected*
0– 4	..	65	..	55 (*84%*)
5– 9	..	76	..	62 (*82%*)
10–14	..	56	..	30 (*54%*)
15–24	..	146	..	73 (*50%*)
25–39	..	113	..	47 (*42%*)
40 plus	..	44	..	17 (*40%*)
Total	..	500	..	284 (57%)

Types of Lesion.—As might be expected, primary infection of the lung and enlargement of the draining lymph-glands was common in the early age-groups, whereas hæmatogenous foci were seen at all ages, but especially in adults. The bronchogenic type of tuberculosis was seen infrequently, partly because these cases were denied admission to the hospital and partly because the bone lesion, being a result of a hæmatogenous dissemination, is more likely to be associated with other hæmatogenous foci in various parts of the body, including the lungs. Table II summarises the type of lesion found in the different age-groups and the percentage of that particular lesion in each age-group.

Table II shows that 31% of the patients showed one or other component of the primary complex, 27% showed hæmatogenous lesions, and 3% showed bronchogenic lesions. If these figures are analysed further, according to the total number of patients in the different age-groups, it becomes obvious that:

(1) The commonest lesion in patients under 15 years of age is the primary complex present in 70%.

(2) The younger the child, the higher is the percentage of those showing the primary complex.
(3) The younger the child, the more likely is the radiogram to show not only the large mediastinal glands but also the primary lung infiltration.
(4) The commonest lesions in adolescents and adults are the hæmatogenous foci, present in 40% of the patients over 15 years of age, only exceptions showing one or both components of the primary complex.
(5) The small number of patients with the bronchogenic type of tuberculosis are found in the older age-groups.

The significance of these findings is discussed below.

Localisation of Pulmonary Lesions.—Table III summarises the localisation of the pulmonary lesions discovered and shows that the primary lung infiltration and the adult type of tuberculosis were, on the whole, unilateral, whereas glandular enlargement and hæmatogenous foci were usually bilateral.

TABLE III—LOCALISATION OF PULMONARY LESIONS

Lesion	No. of cases	Right upper zone	Right lower zone	Left upper zone	Left lower zone	Bi-lateral
Primary lung infiltration	84	21 (*25*%)	27 (*32*%)	20 (*24*%)	16 (*19*%)	0
Glandular enlargement . .	154	33 (*22*%)		43 (*28*%)		78 (*50*%)
Hæmatogenous foci	131	21 (*16*%)	4 (*3*%)	33 (*25*%)	1 (*1*%)	72 (*55*%)
Bronchogenic	16	5 (*31*%)	0	7 (*44*%)	0	4 (*25*%)

Radiographic Appearances of Lesions.—Most of the primary lung infiltrations presented ill-defined fluffy patches of consolidation leading up by excessive bronchial and vascular shadows to the hilar region. In a smaller number of cases, well-defined shadows were seen, varying in size from a few millimetres to complete involvement of the whole lobe. If healing has taken place, calcification may be seen in these lesions. In one case cavitation occurred in the primary lung infiltration.

The glandular enlargement varied in shape in different individuals. In some it presented a local tumour projecting from the mediastinal shadow or hilum, and in others the enlargement was more diffuse, producing a generalised widening of the mediastinal shadow. These shadows were at times connected by increased bronchial and vascular markings to the primary lung infiltration. Within the shadows calcium deposits may be seen in the form of either granules or larger masses.

The hæmatogenous foci, usually small, varied in size from about 2 to 10 mm. in diameter. They were round or oval, although rectangular shadows running out from the hilum to the periphery of the lung were observed in a few cases. Although in most cases these opacities were ill defined and not homogeneous, a fair number were uniform in density and sharply demarcated from the surrounding normal lung tissue. The lesions, generally multiple, were situated in the upper few centimetres of the lungs at their periphery. In 3 patients they were universally distributed as in typical miliary tuberculosis, and in 10 only one opacity was found. In most of these cases it was well defined and placed in the infraclavicular zone. As these shadows were found in adults, and as the draining glands were not enlarged, they were taken to have originated endogenously from hæmatogenous implantation. Their origin from exogenous reinfection was considered unlikely in view of the simultaneous presence of other hæmatogenous lesions and their pathological course. A feature commonly seen with apical foci was the well-marked reticulation leading down towards the hilum and not associated with enlarged mediastinal glands. These were interpreted as vascular and lymphatic shadows accentuated by drainage of infected areas.

The bronchogenic type of tuberculosis showed the familiar features and will not be enlarged on.

Course of Disease and Prognosis.—Of the 284
who showed active pulmonary lesions, 75% have
or are healing, 15% remained stationary, and 10%
worse. In most cases healing took place by ab
calcification, and fibrosis, leaving behind sta
radiological shadows which were assumed to be he
The reticulation leading from apical foci towards
hilum was usually the last to disappear. On the ot
hand, spread of pulmonary lesions is either by dir
extension or by a new hæmatogenous disseminati
terminating in 3 cases by miliary tuberculosis.

As can be seen from the foregoing, the prognosis of
pulmonary lesions in patients with skeletal tuberculo
is good. Radiologically patients have improved
healed, although no active treatment was given for
lung lesions.

Intrathoracic Complications.—Collapse of part or
whole lobe occurred in 4 patients, aged 2, 3, 4, and 1
in 2 of these collapse was due to enlarged mediasti
glands, and in 2 to paravertebral abscesses encroachi
on lung tissue.

Pleural effusion developed in 10 patients while
hospital. In 4 it was bilateral, and all the patients a
alive and well; 3 of the patients who developed pleuri
showed active pulmonary lesions.

Tuberculous empyema was found in 3 cases. It w
localised and chronic, producing only mild gene
symptoms.

Paravertebral abscesses have burst into the pleu
cavity in 4 cases: 3 penetrating into the lung and formi
bronchopleural fistulæ in 2 cases and a lung abscess in
The abscesses originated in 2 cases from dorsal lesio
in 1 from a cervical lesion, and in 1 from an upper lumb
lesion.

Tuberculous pericarditis occurred in 1 patient, who
slowly recovering.

Necropsies.—8 patients with positive radiologic
findings in the chest died. Of these, 5 died of tuberculo
meningitis, 2 of pulmonary extension of tuberculo
disease, and 1 of pleuropulmonary fistula as a result
the extension of a mediastinal abscess.

Necropsies were carried out on 4 of these. In
aged 4, 10, and 21, a primary complex was found in t
lung. In the fourth, aged 18, only hæmatogenous f
were present, thus confirming the clinical findings.

A caseating Gohn's focus, about 1 cm. in diamet
discovered in the child aged 4, was not visible in any of t
previous radiograms, including one taken a week bef
death.

DISCUSSION

In determining the status of the respiratory system
extrapulmonary tuberculosis the radiological findin
were naturally of paramount value. It is not, therefo
surprising that the main theoretical and practical poi
arising out of this investigation should be based on the
findings, which are discussed in the following paragrap
Certain other points of interest, however, which ha
come to light from the history and other investigatio
carried out on the patients, will be commented on at t
end of this discussion.

Incidence.—The radiological findings in this seri
confirm the intimate relation between pulmonary a
extrapulmonary tuberculosis, as found by other invest
gators (table IV).

Almens and Flesch-Thebesius (1923) reported on 100 childr
with extrapulmonary tuberculous lesions, 53% of who
showed pulmonary lesions. MacKinnon (1924) reported
cases with pulmonary lesions out of 30 patients with extr
pulmonary tuberculosis. Ragolsky (1920) reported that the
were pulmonary lesions in 48 children out of 104 and in
adults out of 96 studied. Unfortunately, his figures inclu
calcified and active lesions.

Hocker (1931) found 63·6% of children with extrapulmonar
lesions to have pulmonary lesions also. Snyder (193
examined a series of adults and children with extrapulmonar

ions; 37·3% of the adults and 44% of the children had ulmonary lesions. Reisner (1934) reported on 240 cases with trapulmonary tuberculosis, 124 (51·7%) of which showed idence of active lung disease.

Meng and Chen (1935) reviewed 100 cases of extrapulmonary berculosis and found 47% of them to have pulmonary lesions. eters (1937) reviewed 95 cases, 60% of whom had pulmonary ions; and Marienfeld (1939) found 24 out of 74 with active ung lesions. Rosencrantz et al. (1941) reported 118 patients ith pulmonary lesions out of 160 with extrapulmonary lesions. Tepper and Jacobson (1943) reported 79 cases with lung sions out of 100 non-pulmonary tuberculous patients. nfortunately, here again healed lesions were included. accarezza and Gomez (1940) studied 420 cases of hæmatoenous tuberculous disease, and found 90% of them with ulmonary disease of the same ætiology.

In the present series 57% of all the patients showed ne or other form of active pulmonary disease, a figure well in agreement with those of the authors just reviewed. This high percentage of pulmonary lesions in patients presenting themselves with skeletal tuberculosis emphasises the generalised nature of tuberculosis. Further evidence of this point was provided by the bacteriological investigations of the renal tract and post-mortem material. The urine of 100 patients was examined microscopically, culturally, and by guineapig inoculation for tubercle bacilli, which were found in 16 cases. In most of these intravenous pyelography was done, and tuberculous lesions in the kidneys were demonstrated.

The few necropsies done in this series confirmed the presence of pulmonary lesions in 4 out of 8 patients and multiple tuberculous lesions in all. A larger series of necropsies on patients who died of skeletal tuberculosis was reported on by the American Orthopedic Committee in 1933; 37% of cases thus examined showed active pulmonary lesions.

The multiplicity of the lesions thus found confirms the modern conception of the natural history of tuberculosis. The importance of searching all organs liable to tuberculosis, wherever the original manifestations appear, annot be over-emphasised.

Type of Lesion.—A further point of interest is the variability of the lesion found in the lungs at the different ages. The commonest lesion in children under 15 years of age is one or other component of the primary complex, whereas later in life this lesion is seen only rarely in association with skeletal tuberculosis. Instead, the hæmatogenous type of tuberculosis is found in the lungs, with no evidence of the whereabouts of the primary lesion responsible for that dissemination.

TABLE IV—ASSOCIATION OF PULMONARY AND EXTRA-PULMONARY TUBERCULOSIS

Investigator	No. of extra-pulmonary cases	No. of pulmonary cases
Adults		
MacKinnon (1924)	30	20 (*66%*)
Ragolsky (1929)	96	62 (*64·6%*)
Snyder (1933)	51	22 (*37·8%*)
Reisner (1934)	240	124 (*51·7%*)
Meng and Chen (1935)	100	47 (*47·1%*)
Peters (1937)	95	57 (*60%*)
Marienfeld (1939)	74	24 (*33%*)
Rosencrantz et al. (1941)	160	118 (*73·7%*)
Tepper and Jacobson (1943) ..	100	79 (*37·3%*)
Vaccarezza and Gomez (1940) ..	420	378 (*90%*)
Total adults..	1366	931 (*68·1%*)
Children		
Almens and Flesch-Thebesius (1923)	100	53 (*53%*)
Ragolsky (1929)	104	48 (*46%*)
Snyder (1933)	41	18 (*47·4%*)
Total children	245	119 (*48%*)
Total adults and children	1611	1050 (*65%*)

Table II shows that the younger the child, the more likely are the primary lung infiltration, enlargement of the draining mediastinal glands, and the bone lesion to be found at the same time in the same patient. In the older child the advance of the tuberculous process from lung to glands into the blood-stream and bone is slowed down. By the time the skeletal lesion is manifested clinically, the primary lung infiltration has healed, and the enlarged mediastinal glands remain as the only evidence of the natural course of the disease. Many children and adults succeed in localising the infection to the chest. The thoracic lesion may or may not produce clinical symptoms, but in either case partial healing has taken place. A period of well-being then follows, lasting a variable number of years. With the advent of puberty and economic hardship, the primary lesion is reactivated. A series of pathological processes is started, culminating in hæmatogenous invasion and implantation in skeleton, lung, or kidney, singly or in combination.

It appears, therefore, that the skeletal lesion in children follows quickly the primary lung infiltration and is thus a true post-primary infection. In most adults, on the other hand, the skeletal lesion does not soon follow the primary infection, nor is it a recrudescence of a quiescent post-primary bone lesion. In all probability it results from a reactivation of some other quiescent focus in the body (probably a quiescent primary lesion) which causes blood-stream dissemination of tubercle bacilli and their implantation in bone and lung. This will explain the presence at the same time of the primary complex in the lung and skeletal lesions in children, and the absence of these lesions and the presence of hæmatogenous lung foci in adolescents and adults, especially in the age-group 15–24, as these are exposed to hormonal and economic factors tending to reactivate quiescent primary lesions and to precipitate blood-stream dissemination.

The bronchogenic type of tuberculosis was found in only 16 cases, partly because skeletal tuberculosis, being of hæmatogenous origin, is more likely to be associated with that or an earlier type of lung lesion, and partly because in these cases the lung lesion is the clinically important one and as such is likely to be treated in a sanatorium for chest diseases and not in an orthopædic centre.

Source and Root of Entry of Tubercle Bacillus.—A chain of events similar to that portrayed above will take place if the primary infection is extrapulmonary (mouth or gut). There is no doubt that this was so in many cases of this series, but it is a remarkable fact that such a high proportion should show their primary infection to be in the respiratory tract (see table II). This forces one to the conclusion that skeletal tuberculous infection in children in this part of England at the present time originates from primary tuberculosis in the respiratory tract, this acting as a source of organisms for dissemination by the blood and implantation in the skeleton. As the primary infection is a respiratory one, it obviously enters the lung by inhalation. This points to the human type of tubercle bacillus as the causal organism derived from human pulmonary cases.

The same process can be said to have taken place in adults, although here no direct radiological evidence is available of the route of entry. As has been pointed out, there is reason to believe that the tubercle bacilli responsible for adult lung and skeletal lesions originate in a reactivated primary infection acquired in childhood. There is no occasion to doubt that most of these were respiratory ones, as they have been proved to be in the children of this series. This is further supported by necropsies on children who died of tuberculous meningitis, an extreme example of hæmatogenous dissemination. Blacklock and Griffin (1935), who examined 241 children after death from tuberculous meningitis, found 74% with primary complexes in the lungs. Prof. G. B. Fleming (1943) analysed 100 cases with tuberculous meningitis and found 80 with primary lung infections.

The conclusion that the infecting organism is the human type of tubercle bacillus is supported by the bacteriological investigations carried out on this series by Dr. H. Schwabacher under the auspices of the Medical Research Council. The tubercle bacilli obtained from the sputum and gastric lavage were typed and, as was expected, were found to be of the human variety. More interesting and conclusive are the results obtained from typing the tubercle bacilli derived from pathological material of the skeletal lesions (pus, synovial fluid, &c.) in 88 patients. Of these, 83 (94%) were of the human variety and only 5 bovine.

It can thus be seen that the clinical, bacteriological, and pathological findings all point to the fact that most extrapulmonary tuberculous lesions in this part of England are due to the human type of bacillus, originating from contact with human cases and finding access to the body through the respiratory tract. Milk from infected cows cannot be considered any longer an important source of infection in extrapulmonary tuberculosis, presumably owing to the fact that almost all milk marketed in London and the home counties is pasteurised.

Diagnosis.—Besides the above considerations arising out of the routine study of pulmonary radiograms in skeletal tuberculosis, a great deal of help can be derived from it in the diagnosis of doubtful skeletal lesions and in the prognosis of the established disease. When the tuberculous nature of a skeletal lesion is in doubt, one may discover a pulmonary lesion whose nature is not in doubt. It can then be assumed that both lesions are of the same ætiology. On the other hand, a negative pulmonary radiogram is of little value in the adult, but its diagnostic importance increases in the younger age-groups, in whom up to 84% are expected to show pulmonary lesions, the absence of which will throw doubt on the tuberculous nature of the skeletal lesion.

Prognosis.—The prognosis of a tuberculous lesion can be judged partly by its rate of development from the time of infection to the time of clinical manifestations. If a radiogram of the chest shows the lung and glands to be involved (primary complex), one can assume a rapid advance of the disease from the primary lung infiltration into the draining glands and thence via the blood-stream to the skeletal lesion. The prognosis will correspondingly be poor. In those with a better prognosis the lung infiltration would have been absorbed or calcified, and the draining glands, although enlarged, would show various degrees of healing. Not only is the first radiogram of the chest valuable in estimating the previous course of the disease, but also routine three-monthly radiograms will follow the development of the pulmonary lesion while the patient is under treatment. These usually run a course parallel to that of the skeletal lesion. They will thus confirm the prognosis as judged from the radiograms of the extrapulmonary lesion.

Prevention.—With the knowledge of the source of infection, the route of entry, and the factors liable to cause reactivation of quiescent lesions, a scheme can be formulated for the prevention and control of extrapulmonary tuberculosis:

(1) Elimination of the source of infection by efficient treatment of sputum-positive cases. If this is impossible, contact with children should be avoided.
(2) Early diagnosis and treatment of the primary infection.
(3) Maintenance of body resistance to prevent spread of disease and reactivation of quiescent lesions.

The first and third of these are obvious and need no further comment. The second, however, is worthy of emphasis, as so many authorities have expressed doubt about the desirability of treating the primary infection in children. Although in most of these the infection will run a benign course, some will develop [illegible] tuberculosis. It is felt, therefore, that early trea of the primary infection will pay the community great reduction in morbidity and mortality of pulmonary tuberculosis.

The pulmonary radiological findings have thus provi evidence for many theoretical considerations and pract help in the diagnosis, prognosis, and treatment of ex pulmonary tuberculosis. Other points of interest ari out of the history and other investigations carried on these patients will now be considered.

Sanatorium Treatment.—As was pointed out, 26 patie had undergone sanatorium treatment. In 4 of th cases collapse therapy was instituted. The remain were treated on general lines and responded in compl healing of 12 of the remaining 19 patients. Those r completely healed are progressing favourably. Th facts suggest that the pulmonary lesions were either t primary complex in children or the hæmatogenous ty of lesion in adults, both likely to be associated wi skeletal tuberculosis and both responding well to gene lines of treatment. This conclusion was supported by t few radiograms of the chest obtained from some sanato and by the films of those cases still showing active lesio

TABLE V—INCIDENCE OF PLEURAL EFFUSIONS

Onset in relation to skeletal lesion	No. of cases of pleural effusion	Bilateral effusions	Positi radiogra
Before	43	4	24
During	10	4	4
After	4	0	2
Total ..	57	8	30

The favourable prognosis in this type of pulmona lesion is emphasised by the large number of patien (12) showing normal lung fields within a few years sanatorium treatment. It was, however, surprisi to find the skeletal lesion developing unfavourably these 12 cases, as usually the skeletal and the lu lesions follow the same course. Two factors may ha been responsible: (1) the delay in the diagnosis of t tuberculous nature of skeletal symptoms—these we usually diagnosed and treated as rheumatism, whi implied an added strain on bone or joint; (2) the develo ment of cold abscesses in relation to the skeletal lesio which soon became secondarily infected. In this co nexion it should be emphasised that any skeletal sym toms in a patient known to have tuberculosis must considered of the same ætiology until proved otherwi Repeated radiography and clinical evaluation are essenti if these cases are not to be wrongly diagnosed.

Pleurisy.—Table v summarises the incidence of pleu effusions in this series before, during, and after t development of the skeletal lesion, and the pulmona findings in these patients.

The number of patients who had pleurisy is thus (12% of the whole series); 8 of these effusions we bilateral. Of these bilateral cases, only 1 patient h died of miliary tuberculosis, and 2 others have shown semi-miliary type of lesion, which has, however, regresse slowly to complete absorption. The gloomy progno attributed to bilateral effusions cannot, therefore, b maintained.

It is worth while to emphasise the scarcity of pleur effusions in the younger age-groups. Only 2 patient had pleurisy in the 5–9 and 1 in the 10–14 age-grou The explanation of this fact is obscure. Pleurisy ca thus be said to be an early manifestation of tuberculou infection which may terminate in pulmonary or extr pulmonary lesions. This conclusion has obvious implica tions to those engaged in the prevention and detectio of all types of tuberculosis.

Signs and Symptoms.—The present history and the ysical signs are of little help in determining the presence a lung lesion. The lesions are minimal and no signs symptoms are to be expected.

Sputum and Gastric Lavage.—Only 6 patients had utum positive for tubercle bacilli, partly because of the ematogenous nature of the pulmonary lesion and rtly because no positive cases were admitted. The sult of gastric lavage and guineapig inoculation, wever, came as a surprise. The question arose hether positive gastric-lavage cases could be retained the same ward as non-tuberculous patients. This oblem was rather urgent in the children's ward, where n-tuberculous orthopædic cases were kept together with e tuberculous ones. To determine the point, 3 positive stric-lavage cases were left in the general ward among e non-tuberculous cases. No special precautions were ken. The non-tuberculous cases were Mantoux tested. he positive were excluded, and the negative were tested t three-monthly intervals until discharged. 18 Mantoux-egative cases were in the ward, and the average length f stay was six months. No cases became positive while the ward. It was therefore concluded that tuber-ulous pulmonary lesions producing tubercle bacilli in ch small numbers as to require a guineapig inoculation gastric contents to demonstrate their presence are not clinical source of infection and can be left safely in ntact with non-tuberculous cases. This policy has en followed since that time in this hospital, and no berculous case has developed as a result.

SUMMARY

The respiratory tract of 500 patients with skeletal berculosis was investigated. Of these, 284 (57%) d active pulmonary lesions.

The type of lesion varied according to age. The imary complex was found in most of the children, and ematogenous foci in adults.

The respiratory tract thus appears to be the route of try of the tubercle bacillus even in skeletal tuberculosis.

The infecting organism is therefore most likely to be, clinical grounds, the human type from human open lmonary cases. Milk infected with bovine tubercle cilli, in this part of England, can no longer be con-dered an important source of skeletal tuberculosis, esumably because of its pasteurisation.

The clinical findings were confirmed bacteriologically typing the tubercle bacilli obtained from pathological aterial derived from the skeletal lesion.

The skeletal lesion in most children originates soon ter the primary infection. In most adults it is due to activation of quiescent tuberculous foci resulting in ood-stream dissemination and subsequent implantation bone and lung.

The importance of routine radiography of the chest in e diagnosis and prognosis of skeletal tuberculosis is phasised.

My thanks are due to Mr. J. R. Rocyn-Jones, Mr. E. P. Brock-an, Mr. J. A. Cholmeley, and Mr. E. H. Hambly for rmission to investigate the patients under their care, and to . B. H. E. Cadness-Graves and Dr. H. Schwabacher for the cteriological investigations.

ESSEX COUNTY HOSPITAL, COLCHESTER

A CASE of incompatible blood-transfusion, followed by uræmia, was unsuccessfully treated by all the commonly recognised methods, and finally yielded to decapsulation of the kidneys, the associated uræmia being relieved by the use of the peritoneum as a dialysing membrane.

Incompatible blood-transfusion is followed by reactions which fall into three phases. The immediate reaction develops shortly after the transfusion is begun and varies in intensity with the amount and rapidity of the injection and the sensitivity of the patient. In the more severe cases immediate death takes place, and in the less severe there is a rigor with a bursting headache, tingling in the limbs, pain in the back, great shortness of breath, precordial pain, and sometimes a sense of impending death. If the transfusion is immediately abandoned, the donor cells are lysed, there is hæmoglobinæmia, transient jaundice, and hæmoglobinuria, and the patient after the first shock makes a steady recovery. However, if much incompatible blood is given, the reaction may be much more severe, and it is usual for the patient to pass a moderate quantity of wine-coloured urine containing hæmoglobin (Hb) or acid hæmatin.

The second phase is a latent interval in which the patient improves clinically but passes a very small amount of urine. The third phase is that of renal failure and uræmia, and is followed either by the re-establishment of urine flow and recovery or by death in uræmic coma.

General opinion in the past has been that the anuria is caused by the mechanical blockage of the renal tubules by precipitated blood pigment, the donor's blood being lysed and the Hb excreted through the kidneys, where, in the presence of acid urine, it is deposited as insoluble acid hæmatin. In rabbits the urine is always alkaline and hæmoglobin is excreted unchanged and without renal damage. Baker (1937) stated that the Hb must either pass out through the glomerular filter or be excreted by the tubules; in either case it arrives in the lower convoluted tubules, where the urine is concentrated. In the presence of a sufficiency of salt and in an acid medium the Hb is deposited as acid hæmatin, which is seen microscopically as a brown granular precipitate. Baker concluded that, with a concentrated urine which precipitates Hb, there were three possibilities, depending on the amount of Hb excreted and on the degree of concentration of urine: (1) with a considerable Hb excretion and a very concentrated urine, there is a massive precipitation of hæmatin in the renal tubules, which packs down in masses, causing permanent blockage leading to complete anuria; (2) with a moderate amount of Hb or a more dilute urine, the precipitate is less copious and produces a temporary obstruction, which is followed by the gradual extrusion of hæmatin casts and diuresis; (3) with still less Hb or a very dilute urine, a little hæmatin is precipitated in the renal tubules and is easily passed out, often as granular casts, and no gross functional damage to the kidney results.

Trueta et al. (1946) have discovered that the renal blood-flow is profoundly influenced by nervous stimuli, the result of central or peripheral action by various noxious agents, and have shown in experimental animals that under certain conditions the renal circulation continues through the medulla while the cortex is ischæmic and the urine-flow completely suppressed. These workers, who were investigating the mechanism of crush syndrome, suggest that urine suppression due to sulphonamides, incompatible blood-transfusion, Weil's disease, and some forms of nephritis is due to a defence mechanism by which the cortex of the kidney is excluded from the circulating toxin by an intrarenal vascular shunt. While this recent work is of profound significance, the generally accepted view today is that renal suppression resulting from incompatible blood-transfusion is caused by the blockage of the renal tubules by massive deposits of hæmatin crystals.

Post-transfusional anuria leads either to death in uræmic coma or to diuresis and recovery. As salvation lies in diuresis and nothing else, treatment has consisted of the ingestion of huge quantities of fluid, of alkalinisation of the blood in the hope that the obstructing acid hæmatin may dissolve, of washing out the renal pelvis with hot lotions, and of spinal anæsthesia to exclude nervous stimuli and so relieve the renal vascular spasm. Finally, decapsulation of the kidneys has claimed a few triumphs. In the case here recorded the various therapeutic measures were tried in order with, so far as possible, clear-cut intervals to observe their separate effects.

In the third or uræmic phase of suppression the blood-urea level rises daily, and it seems reasonable to assume that, since the renal damage may be reversible, any measures which would tide the patient over uræmia and avoid the fatal coma while the blocked kidneys cleared might be life-saving. Unknown to us, the use of the peritoneum as a dialysing membrane was investigated in experimental animals by Putnam in 1923, and the method had actually been used clinically by Seligman et al. (1946) to relieve uræmia. These workers treated with success a case of sulphathiazole renal suppression by irrigating the peritoneal cavity with large quantities of a specially prepared solution. After fourteen days of virtually complete anuria renal function was fully restored, but not before large quantities of urea had been removed from the blood by peritoneal dialysis. A method similar to that described by Seligman et al. was used in the case here reported.

CASE-RECORD

A married woman, aged 37, was admitted to hospital on March 17, 1946, with anæmia due to menorrhagia, and a blood-transfusion was advised as she had not responded to ordinary remedies. The patient's blood and her husband's having been grouped and reported to be A2 and O4 respectively, a blood-transfusion was started by slow intravenous drip at 5.30 P.M. on the 21st.

After 30 c.cm. of blood had been given, the patient felt hot and very short of breath and complained of pain in the lower abdomen. Something like a rigor developed, and the patient vomited, but 5 minims of adrenaline was given and the transfusion completed, a total of 350 c.cm. of blood and 80 c.cm. of citrate solution being given. During the night there was further vomiting and some diarrhœa.

Next day premature menstruation had started, and 350 c.cm. of wine-coloured urine with a heavy deposit was withdrawn by catheter. In view of this danger signal rectal glucose saline was begun, and the patient was catheterised at 6 P.M., when 120 c.cm. of clear urine was withdrawn.

As the patient had vomited all fluid taken by mouth, 2% sodium bicarbonate in water was substituted for the glucose saline per rectum. In all, about 1200 c.cm. of fluid was absorbed from the rectum, and 1 drachm of sodium bicarbonate was given by mouth every hour during the day, but most of it was returned.

The patient meanwhile developed herpes of the lip, headache, and restlessness. Both specimens of urine were acid and contained large quantities of albumin and blood.

On the 23rd it was reported that the patient had had a fair night, and she was catheterised at 6 A.M., when 120 c.cm. of cloudy yellow urine was withdrawn. The rectal drip was continued, and the patient took 2500 c.cm. of fluid by mouth and an hourly dose of 1 drachm of sodium bicarbonate, but half the fluid was vomited. An intravenous drip of 5% in water was started in the morning and continued duri next few days. Further catheterisation in the late afterno yielded 60 c.cm. of clear urine.

On the 24th the general condition remained unchanged but, as thrombophlebitis had started in the arm, the cannu was changed to the left leg. The intake of fluid by mout was 2500 c.cm. containing 17 drachms of sodium bicarbona but the patient vomited about 600 c.cm. In twenty-four hou 2500 c.cm. of glucose in sterile water was given intravenousl and the patient passed 60 c.cm. of clear urine.

Œdema of the face, ankles, and hands now appeared, b the lungs were clear and the bowels freely open. The bloo urea level was 120 mg. per 100 c.cm., and the urine acid a containing albumin. The blood-grouping was reinvestigat and it was found that the patient's group was O4 and th husband's A2.

On the 25th the patient had some epistaxis and menstru loss. About 2000 c.cm. of fluid was retained by mouth, and similar quantity of intravenous glucose saline was given i twenty-four hours. The patient perspired a little and had slight rigor, and catheterisation produced 70 c.cm. of clea urine.

On the 26th the patient's general condition remained th same, but she was rather more drowsy, and the administration of glucose in water was continued, 3000 c.cm. being give intravenously and about 1300 c.cm. by mouth.

At this juncture one of us (R. R.) saw the patient an recognising the possibility of arterial spasm as a factor in th suppression, gave a light 'Percaine' spinal anæsthetic up t the level of the 6th dorsal vertebra. The cerebrospinal flu was clear and not under increased pressure. This manœuv had no beneficial effect, as only 30 c.cm. of urine was recovere during the next twelve hours. The blood-urea level had rise to 153 mg. per 100 c.cm.

On the morning of the 27th there was little alteration in th patient's general condition, but the œdema had increased and there was definite renal tenderness on both sides. On th day 100 c.cm. of sodium sulphate 4% was given intravenously together with gr. 7·5 of caffeine sodium benzoate. Th treatment was repeated later in the day, but without avail The total fluid intake by oral and parenteral routes was abou 3000 c.cm. By next day there had been no response to diuretics, and the fluid intake was continued by mouth. In all about 40 c.cm. of urine was withdrawn by catheter. The blood pressure was 170/100 mm. Hg.

On the 28th the patient was transferred to the Essex County Hospital, Colchester, and on admission she was somewha vague and drowsy but answered questions moderately wel and seemed comfortable.

She was pale and had slight cyanosis of the lips, especially on effort. Her face and eyes were puffy, and there were pin patches on her cheeks. There was well-marked œdema o the hands and one arm. The cranial nerves were normal; th optic disks were not seen. There was good chest movement and nothing abnormal was detected in the cardiovascula system. There was considerable œdema on the back of th trunk, and both lung bases were dull, with diminished ai entry as far up as the angle of the scapula. The abdomen wa slightly distended and the skin œdematous, and there was dullness in the flanks but no more definite signs of ascites. Ther was well-marked renal tenderness on both sides behind an in front.

On the 29th patient's and donor's blood were examined, an a cross match showed agglutination; the patient's blood wa Rh-negative, and no anti-Rh bodies were found in her serum. The blood-urea level was 253 mg. per 100 c.cm., plasma-chlorides level 0·47 g. per 100 c.cm., plasma-protein level 0·5 g per 100 c.cm. A blood-count showed no abnormality; Hb 82%

Cystoscopy showed a normal bladder and orifices, and catheters were passed up to both renal pelves. Hourly washing with saline solution was started but soon caused pain and did not relieve suppression.

By 9 P.M. the patient's general condition was deteriorating; she was more pale and drowsy, with considerable œdema of the face and subcutaneous tissues in general. Renal tenderness was very marked; and, as no benefit had accrued from all the treatment so far tried, it was decided that the only hope lay in decapsulation of the kidneys.

Operation.—Under gas-oxygen-ether anæsthesia (Dr. Douglas Clendon) the patient was turned on her left side and the right kidney rapidly exposed by an th rib bed. Œdema of the skin, muscle, and perinephric sues was very pronounced. Decapsulation was performed. e patient was then turned over and a similar operation ne on the opposite side. Both kidneys presented the same pearance: about twice the normal size, dark blue, and as m as a tennis ball but less elastic. The capsules seemed ry tense, and pale-blue friable kidney bulged through the es of incision owing to increased intracapsular pressure. e left kidney almost exploded and piece of friable tissue re taken for microscopy. Both wounds were sewn up th through-and-through interrupted steel wire sutures, and e perinephric space was drained.

At the end of the operation the patient's neral condition s satisfactory, and a small incision was made into the ntoneal cavity at the extreme anterior end f the left renal ision, and into this a self-retaining Foley catheter was erted. To this was attached a dripper arrangement whereby ice normal saline solution with penicillin was run into the ntoneal cavity at the rate of 60 drops a minute

On the 30th the patient's general condition was poor, and e was more drowsy. During the night 2500 c.cm. of twice-rmal saline had been run into the peritoneal cavity, and e patient complained of distension and colic pain.

There was obvious ascites, and at 10 A.M. the catheter was sconnected from the dripper flask so that the ascitic fluid uld run out into a receptacle. This fluid which escaped th much relief to the patient, was lemon yellow, turbid, ghtly alkaline, and slightly glutinous, and amounted to 60 c.cm. It contained a fifth of its volume of albumin; a posit of pus with occasional red cells; urea 0·255 g. per c.cm.; and chlorides 0·526 g. per 100 c.cm.

By next morning the patient was passing water freely, and general œdema was melting away, the facial changes ing most marked, and moist sounds had disappeared from chest. During this day 350 c.cm. of urine was collected, d much passed into the bed from the bladder and the eration wounds. The blood-urea level was 200 mg. per) c.cm.

In the first twenty-four hours following decapsulation 00 c.cm. of twice-normal saline was introduced into the ntoneal cavity, and 1860 c.cm. of fluid was withdrawn. The urea content of the efflux was 255 mg. per 100 c.cm., indicating that 4·7 g. of urea had been eliminated by dialysis through the peritoneum.

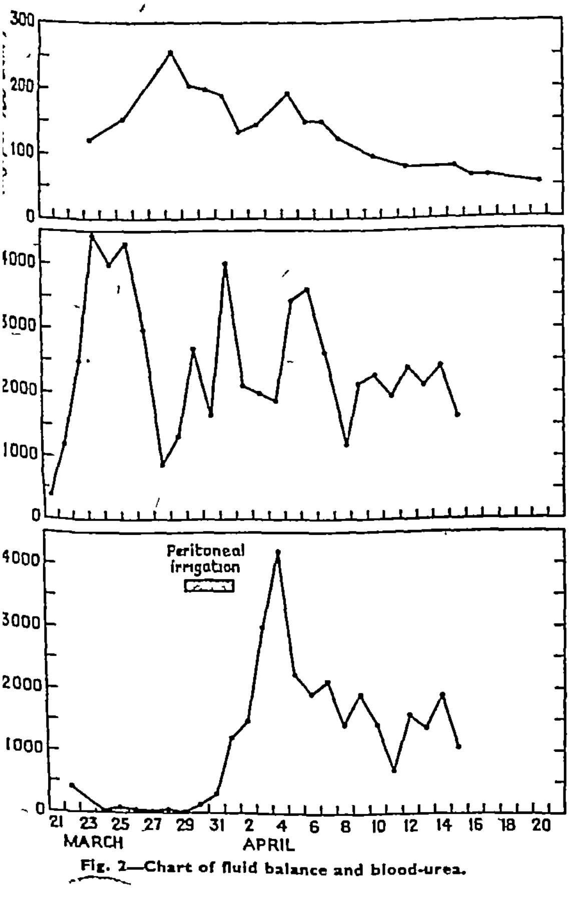

Fig. 2—Chart of fluid balance and blood-urea.

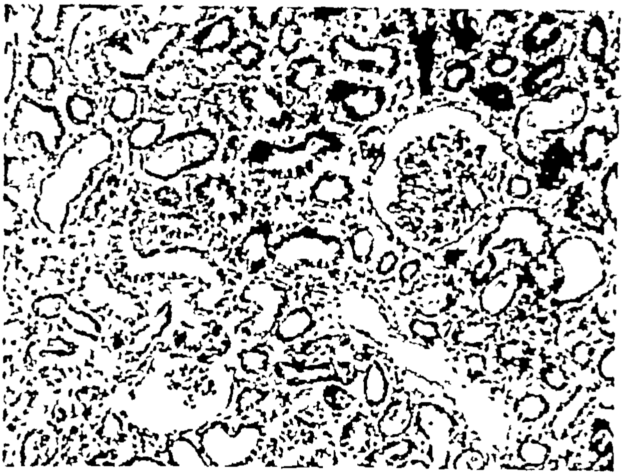

Fig. 1—Section of renal cortex, showing œdema, with occasional small foci of polymorphs and round cells in the interstitial tissue; degeneration of the tubular epithelial cells; and blockage of some tubules with a brown granular pigment. Hæmatoxylin and eosin. (×95.)

In the next twenty-four hours 3000 c.cm. of twice-normal saline was run into the peritoneal cavity, and 660 c.cm. of fluid was recovered, but there was a considerable unmeasured leakage round the tube. The urea content of the efflux was 262 mg. per 100 c.cm., indicating that 1·73 g. of urea had been eliminated through the peritoneum.

Thus in the first forty-eight hours of peritoneal irrigation 6·4 g. of urea was recovered in the collected efflux, and it is certain that more urea was eliminated, because much fluid was lost by leakage round the peritoneal catheter.

Next day the patient's general condition was very much improved, and the blood-urea level was 200 mg. per 100 c.cm. A further 1800 c.cm. of twice-normal saline was introduced into the peritoneal cavity, and only 30 c.cm. of fluid was recovered, but there was probably considerable leakage.

By this time the tube had become blocked or sealed off, so it was removed. From the small incision clear serous fluid leaked for five or six days. The blood-urea level on this third postoperative day was 180 mg. per 100 c.cm. and on the fourth postoperative day 130 mg. per 100 c.cm.

Clinically the patient had improved beyond all expectation. She was bright, her skin was in much better condition, and the œdema had disappeared. She was no longer drowsy, was coöperative, and took food and drink by mouth.

Blood-urea estimations were carried out daily, and the blood-urea level rose sharply after drainage of the peritoneum had ceased to be effective, and it continued to rise for three days before it began to fall coincidentally with the increase in urine output and in urinary urea.

By April 23 the patient's blood-urea was 30 mg. per 100 c.cm. and the urine urea and chloride estimations were normal, and a week later the patient was discharged, having made a full recovery.

DISCUSSION

This case is another example of the well-known picture of anuria due to mismatched transfusion. Uræmia is not a sufficiently broad term to define the consequences of urinary suppression because not only is urea accumulated in the body but also other nitrogenous substances, water, salts, and perhaps many more substances are retained, to which are also added those materials introduced therapeutically. The rise in blood-urea level is a gross and obvious change, and to this too much attention may easily be accorded. Though not so readily detected, changes in the delicate balance of blood chemistry and water metabolism must not be overlooked, especially when they come under the influence of peritoneal dialysis, lest measures to reduce the amount of blood-urea may so disturb general metabolic processes that life is endangered rather than protected by the enthusiastic therapist.

In the treatment of anuria, whether due to mismatched transfusion, sulphonamide blockage, "crush syndrome," or other cause, first place has been given to the administration of huge quantities of fluid, often containing sodium chloride and alkalis, and by this procedure much water and salts are added to the body fluids already embarrassed by the kidney failure. The disturbance of osmotic pressure causes œdema, and the retention of phosphates and other substances may cause acidosis and a fall in serum-calcium level. At first the body can withstand the abnormal conditions, but later certain changes in the blood chemistry show that stability can no longer be maintained. In our case the patient had severe general œdema, which was probably not without its effect on the pulmonary, cardiovascular, and central nervous systems. This œdema was nowhere more severe than in the kidneys exposed at operation; and, whatever the essential cause of anuria, we believe that renal œdema, which is so clearly shown in the microscopical section (see fig. 1), further embarrassed the blood circulation. The section of the kidney shows the typical picture of tubular damage and deposits of pigment, and œdema is also very obvious. We feel that this last factor has been given too little consideration in the past, and that efforts to produce diuresis by forcing the fluid intake may be a two-edged weapon.

With regard to the local treatment of the kidneys, beyond general efforts to promote diuresis, we think that in our case none of the procedures adopted before decapsulation had any beneficial effect, and that the operation was justified by the subsequent diuresis. The expansion of the kidneys following section of the capsule was most impressive, and suggests that the relief of tension was an important factor in renal recovery.

We believe that the use of the peritoneum as an excretory organ played an important part in the recovery, the beneficial results being shown by the steady fall in blood-urea level while the peritoneal irrigation was efficient, and by the large quantity of urea—i.e., 7 g.—recovered from the peritoneal efflux. Unfortunately much of this efflux was lost, and the true efficiency of the method could therefore not be measured. The fact that after the failure of peritoneal irrigation the blood-urea level rose and then fell again with increasing diuresis is further evidence that the peritoneum allows easily diffusible substances, such as urea, to pass from the circulating blood into an artificially created ascites. Taking as a conservative estimate the amount of urea eliminated by this method in forty-eight hours as 6·4 g., and knowing the blood-urea level to be at that time 200 mg. per 100 c.cm., we can assume that, the blood-volume being 5 litres, roughly 3·2 litres of the blood were cleared of urea in two days. During this period the patient's blood-urea level fell from 200 mg. to 136 mg. per 100 c.cm., a drop of 64 mg. per 100 c.cm. On the assumption that the patient's blood-volume was 5 litres, this change represents a fall in the total blood-urea of 3·2 g., and the discrepancy between this figure and the 6·4 g. eliminated by peritoneal dialysis and urea in the urine is explained by the mobilisation of urea from the tissues into the blood.

The accompanying table and fig. 2 show the changes in fluid intake and output and in blood-urea level during most of the patient's stay in hospital, and it can be reasonably inferred that the use of the peritoneum as a dialysing membrane had an important influence in reducing the blood-urea level before the establishment of diuresis. One of the most interesting points shown by the pathological findings is the rise in blood-urea level after the peritoneal irrigation became inefficient owing to blockage of the tube. Possibly the introduction of 7 litres of twice-normal saline into the peritoneal cavity reduced the volume of the intravascular fluid by osmotic pressure, and that affected the kidney by relieving œdema. The state of the kidneys at operati and the diuresis after relief of intracapsular tension mal it possible that any reduction of general œdema by t twice-normal saline introduced into the peritoneu *would have an especially beneficial effect on the kidney* That the amount of intravascular fluid was decreased i not considered likely, because of the 4000 c.cm. of flui put into the peritoneal cavity in the first twenty-fo hours only 1860 c.cm. was recovered. As there was n much leakage at this time, much of the twice-norm saline must have been absorbed, and this is support by the rise in the level of plasma and urinary chlorid (see table).

FINDINGS IN BLOOD AND URINE

Date	Plasma chlorides (g./100 c.cm.)	Urine chlorides (g./100 c.cm.)	Plasma protein (g./100 c cm
March 29 ..	0 47	..	6 5
" 30 ..	0·47	0·59	..
" 31 ..	0·59	0·88 0 94 0·46	6 45
April 1 ..	0 67	0·46 0·24 0·46	6·1
" 4 ..	..	0·35	..
" 6 ..	0·59	0 38	..

Period of peritoneal irrigation lasted from March 30 to April inclusive.

In our case peritoneal dialysis was effected b *inducing an artificial ascites*; but, except for the fi twenty-four hours, very little of the introduced flu was recovered from the peritoneal cavity. The fluid w slightly turbid and alkaline, and contained a fifth of i volume of albumin, with pus and occasional red cell which shows that twice-normal saline irritates t peritoneum. From the blood-stream 6·4 g. of urea w cleared, and there is no doubt that changes in chlorid and other substances took place, the exact extent which we could not determine. We considered t possibility of introducing two tubes into the peritone cavity so that a continuous stream might flow throug but thought such a procedure might gravely upset t general metabolism, and we were unwilling to take an risks in a patient who was apparently on the way t recovery.

We publish this paper not only as a chronicle of t treatment of a case of post-transfusional suppression urine but also as the record of a clinical experiment which owing to the pressure of events, could not be carried ou with anything like proper scientific precision, but whic nevertheless has lessons for the future. First, we believ that the massive intake of fluid recommended in th treatment of renal suppression is not without danger and that generalised and more especially localised rena œdema may embarrass rather than encourage the retur of renal function. Secondly, we have found that th commonly recommended local treatments to the kidney were useless, except decapsulation, which in our ca proved to be the deciding factor in recovery. Thirdly we have found that peritoneal irrigation is effective i reducing the blood-urea level when it is raised abnormally high, but how long the irrigation can be maintained w do not know. Our conclusions support those of Seligman et al. (1946), to whom, so far as we know, goes the credit of introducing this method of treating uræmia. The method appears to be particularly suited to cases o reversible renal damage where there is a reasonable hope that the kidneys may recover sufficiently to support life.

Our irrigating tube became blocked soon after treatment was initiated, and this may be due to our use of twice-normal saline, which seems to have set up a considerable peritoneal reaction, and it is probable that adhesive peritonitis finally put an end to the treatment. In the future it may be that fluids will be devised which will enable irrigation to be continued longer.

Finally, though this method appears to be satisfactory in reducing the blood-urea level, its effect on the delicately balanced metabolism must not be forgotten, because the irrigating fluid is in such close contact with the vascular bed that changes may take place through the peritoneal membrane so rapidly as to endanger the patient's life. Until further evidence, clinical and experimental, is forthcoming about the changes which take place through the peritoneum, the method should be used with the greatest care and only when other and more simple procedures are likely to prove ineffective.

SUMMARY

Incompatible blood-transfusion may be followed by uria and uræmia.

Post-transfusional anuria leads either to death in æmic coma or to diuresis and recovery. Treatment erefore aims at diuresis.

In the present case various forms of such treatment ere given, including alkalis, plenty of fluids, both by outh and intravenously, spinal anæsthesia, diuretics, d renal decapsulation.

Finally, twice-normal saline solution was given intraeritoneally by drip injection, and later the fluid was ained off. By this method much urea was eliminated y dialysis through the peritoneum, with relief of æmic symptoms. The patient fully recovered.

We wish to thank Prof. John Beattie, of the Royal College f Surgeons, for encouragement and valuable criticism.

ACUTE INFECTIOUS MONONUCLEOSIS
COMPLICATED BY ENCEPHALOMYELITIS
REPORT OF A CASE

SIMCHA GELIEBTER
M.D. Milan, L.R.C.P.E
ASSISTANT MEDICAL OFFICER, L.C.C. HIGHGATE HOSPITAL

ONLY about a dozen cases of acute glandular fever infectious mononucleosis) exhibiting central nervous omplications have been described. Johansen (1931) eported "serous meningitis," and Epstein and Dameshek 1931) "involvement of the C.N.S." in glandular fever. Johansen's case presented meningeal signs, but the erebrospinal fluid (C.S.F.) showed very little change. Epstein and Dameshek's was a typical case of glandular ever, except that the cerebral symptoms overshadowed the general disease; and even here the C.S.F. showed only an increase in cells (lymphocytes) and little increase in the protein content. Tidy (1934) mentioned the possibility of meningeal complications. Viets and Watts (1929) reported aseptic meningitis, and Schmidt and Nyfeldt (1938) meningo-encephalitis as complicating glandular fever. During an epidemic of mononucleosis Halcrow et al. (1943) investigated 296 cases, among which only 5 patients had meningeal symptoms severe enough to require lumbar puncture. In 4 cases the C.S.F. pressure was increased; 3 out of 4 had a cell-count of more than 5 cells per c.mm., and 1 had a normal cell-count. Landes et al. (1941) described central nervous manifestations, their case being especially interesting because of the cell-protein dissociation. Fledelius (1935) reported paresis of the inferior rectus muscle of the left eye.

An unusual case of infective mononucleosis with varied nervous complications was seen recently in this hospital.

CASE-RECORD

A girl, aged 10 years, was admitted with a history of having had, three weeks before admission, a sudden swelling of her cervical lymph-glands, accompanied by general malaise. She was not seen by a doctor but was put to bed for a week, after which she complained of general weakness. Her mother noticed at this time a slight swelling of her eyes and face. The patient was seen at the outpatient department of a hospital, where "acute tonsillitis" was diagnosed and the mother was advised to put the child back to bed. Two or three days later the patient had several attacks of vomiting without apparent cause; after three more days she tried to get up again but felt too tired, her general condition and appetite being poor. On the day before admission she again had repeated attacks of vomiting, and pain developed in legs, thighs, and shoulders. She was seen by a doctor, who sent her here with a tentative diagnosis of acute rheumatic fever.

On admission her general appearance was poor; facies thin and sallow; tongue furred but moist; fauces clean; tonsils neither enlarged nor inflamed; slightly enlarged lymph-glands in both posterior triangles of the neck, especially on the left side. No displacement of trachea. Nothing abnormal detected in the cardiovascular system, lungs, or abdomen. No meningeal signs, no muscular weakness. Temperature normal, pulse-rate 96, respirations 20 per min. The movements of all limbs were good, but there was slight pain in joints and muscles on brisk movement. A provisional diagnosis of subacute articular rheumatism was made.

Investigations.—Throat swab: Klebs-Löffler bacillus not isolated; gram-staining of film and culture showed mainly *Strep. viridans* and no hæmolytic streptococci.

Erythrocyte-sedimentation rate (E.S.R.): 4% in 1 hour.

Blood-count: red cells 5,310,000 per c.mm., Hb 96%, colour-index 0·91; white cells 5500 per c.mm. (neutrophil polymorphs 13·5%, lymphocytes 82·5%, large mononuclears 4%).

Radiography of chest: no pulmonary lesion evident.

Urine: nothing abnormal detected.

In the 5 days after admission there was little change in her general condition. Muscles and joints were still aching, but the temperature was not raised. On the 6th day there was an evening pyrexia of 99° F.

On the 7th day the patient was lethargic, refused food, complained of pain in both hips and shoulders, would not sit up, lay on her right side, and was very reluctant to move about, but had no vomiting, photophobia, or squint. Examination revealed neck rigidity and a bilateral positive Kernig's sign. Lumbar puncture gave a clear C.S.F., under increased pressure, containing 9 lymphocytes and 6 red cells per c.mm.; total protein 400 mg. per 100 c.cm.; a large excess of globulin; chlorides 740 mg. per 100 c.cm.; no tubercle bacilli or other bacteria; culture was sterile. It was then thought that the case was possibly one of tuberculous meningitis.

On the 8th and 9th days there was no change in the general picture. Evening pyrexia of 99° F. During the night of the 9th day there was a transient diplopia lasting half an hour. On the 10th day there was diplopia for an hour.

On the 11th day neck rigidity was still well marked; Kernig's sign positive; and muscular power of right arm weaker than left. The biceps, triceps, and supinator reflexes were present and equal on both sides; upper abdominal reflexes present, lower weak; ankle jerks and plantar responses doubtful. No squint, headache, or incontinence. Hyperæsthesia and hyperalgesia of muscles of thighs and calves. Optic disks showed no papillœdema, exudate, or hæmorrhage. Temperature 99° F in the evening. Lumbar puncture gave clear C.S.F. under a pressure of 110 mm. H_2O, containing 5 lymphocytes and 67 red cells per c.mm.; total protein 400 mg. and chlorides 790 mg. per 100 c.cm.; culture sterile.

The 12th day followed a quieter night; not so much pain now, but all the above-mentioned signs were more pronounced than before, and in addition there was a general weakness of the muscles of the trunk; patient could not sit up even if supported. The shoulders were apparently weaker than the other parts. The right knee jerk and both ankle jerks were absent. Acute poliomyelitis was now considered as the diagnosis.

This condition continued until the 17th day, when patient felt better and could move her trunk and legs very slightly, but Kernig's sign was still positive. A white-cell count gave 3400 leucocytes per c.mm. (neutrophil polymorphs 25%, eosinophil polymorphs 1%, basophil polymorphs 1%, lymphocytes 68%, large mononuclears 5%). Paul-Bunnell test positive (1–256).

General movements improved still more on the 18th and 19th days. Lumbar puncture showed again a clear C.S.F., under a pressure of 100 mm. H_2O, containing 5 lymphocytes per c.mm.; total protein 250 mg. per 100 c.cm.; a moderate excess of globulin; chlorides 740 mg. per 100 c.cm.; culture negative. Wassermann and Lange reactions negative.

On the 25th day patient could sit up unaided up to 45°–60°, moving both arms well and without pain, but could not extend legs on flexed thighs. Hyperalgesia still present; right knee jerk and both ankle jerks absent.

Improvement continued on the next two days, and a white-cell count gave 4000 leucocytes per c.mm. (neutrophil polymorphs 27%, eosinophil polymorphs 6%, basophil polymorphs 1%, lymphocytes 61%, mononuclears 5%). E.S.R.: 7% in 1 hour.

On the 34th day all signs were rapidly disappearing, but knee and ankle jerks not yet present. Paul-Bunnell test positive only up to 1–32. The patient was attempting to stand but still had some pain on doing so. Lumbar puncture on the 35th day gave a clear fluid, under pressure of 85 mm. H_2O, containing 2 leucocytes per c.mm.; total protein 100 mg. per 100 c.cm.; a slight excess of globulin; chlorides 725 mg. per 100 c.cm.; culture sterile.

On the 40th day right knee jerk and both ankle jerks now very weak; patient able to walk slowly with legs divaricated. On the 44th day jerks normal and equal, patient walking much better. On the 49th day gait almost normal. A white-cell count gave 5000 leucocytes per c.mm. (neutrophil polymorphs 23%, eosinophil polymorphs 1%, lymphocytes 69%, large mononuclears 7%).

On the 51st day gait was normal and the patient was free from all symptoms.

DISCUSSION

This case appears to be one of glandular fever in which the central nervous system was severely affected, followed by complete recovery. The Paul-Bunnell test was strongly positive (1–256) at the height of the nervous affection and became barely positive when the neurological signs had practically gone. Of particular interest is the fact that during the whole course of the disease there was a persistent leucopenia. At no time were the white cells more than 5500; the lowest figure was 3400. The mononuclears were never more than 7%, the maximal lymphocytosis was 82·5%. Tidy (1934) writes: "It is evident that the virus of glandular fever transiently affects all the blood-forming tissues—and no single blood picture is typical of the disease."

The C.S.F. never contained more than 9 lymphocytes per c.mm., even when the protein was 400 mg. per 100 c.cm. One might perhaps deduce that the small increase of white cells in the C.S.F. (and the consequent cell-protein dissociation) was ætiologically related to the leucopenia. This relationship, however, has still to be proved, just as much as the reputed relationship between the increase of leucocytes in the blood and in the C.S.F. On the other hand, the protean manifestations of the neurological lesion point to the fact that the brain and the spinal cord were involved. This should therefore be considered as a case of encephalomyelitis complicating an acute mononucleosis of a rather unusual type.

Had the sheep-cell agglutination test not been performed, the cause of the illness might have been missed. It is certainly worth while having a Paul-Bunnell test done in all cases showing acute neurological manifestations without apparent cause.

SUMMARY

An unusual case of glandular fever exhibiting widespread involvement of the central nervous system is described. The signs and symptoms were of the type seen in encephalomyelitis. Complete recovery followed.

I wish to thank the Medical Officer of Health, L.C.C., and Dr. J. O. Reid, medical superintendent of Highgate Hospital, for permission to publish this case.

REPEATED ABORTIONS, MISCARRIAGES, AND STILLBIRTHS

VALUE OF ANTISYPHILITIC TREATMENT

RAYMOND G. CROSS
M.D. N.U.I., M.R.C.P.I., M.A.O., M.R.C.O.G.
LATE ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN

THE incidence of repeated abortions, miscarriages, or stillbirths is low.[1] The 54 cases reviewed here are the total number encountered in three years in the antenatal department of the Rotunda Hospital, during which time the hospital was responsible for 15,780 deliveries,[2] making the incidence in this series less than 0·4%.

In 1924–27, during the assistant mastership of Dr. N. McI. Falkiner, the present master of the Rotunda Hospital, it was the practice of the hospital to treat syphilitic mothers at a special clinic in the antenatal department. Excellent results were achieved in patients with a positive Wassermann reaction and a history of repeated stillbirths. The report on the blood reaction of some of the patients suspected of having syphilis was doubtful, the result reading "doubtful positive, please repeat" or "doubtful negative, please repeat." These patients were given full antisyphilitic treatment, as if their blood reaction had been positive, and most of them gave birth to live babies.

It then occurred to Dr. Falkiner that a patient with a history of repeated abortions and a negative Wassermann reaction might respond equally well to full antisyphilitic treatment, and from that date this treatment has been applied to all cases with a history of repeated abortions, whether the Wassermann reaction is positive or not. The present 54 cases were seen and treated by me during my period as assistant master (May, 1941–44).

Antisyphilitic treatment with organic arsenicals is not without attendant risks, and in 1941–44 some cases of severe jaundice after treatment with these drugs were reported in private communications. It was therefore decided to change to 'Bisoxyl,' which carries far less risks and does not seem to be any less effective in preventing stillbirths.

MANAGEMENT

The routine management of cases of repeated abortion, miscarriage, or stillbirth is as follows:

Investigation.—After the careful recording of the patient's general and marital history, including a statement of the frequency of intercourse and the time of the menstrual cycle at which intercourse mostly takes place, a complete general medical examination is made, with special emphasis on syphilis, diabetes, and hypothyroidism. This is followed by gentle bimanual examination to exclude malposition and malformation of the uterus and by inspection of the cervix with a bivalve speculum to exclude laceration, &c. Finally, specimens of blood and of breast fluid are taken for estimation of the Rh factor.

---

[1] Abortion is used to mean expulsion of the ovum before the time of the formation of the placenta (i.e., during the first 3 months); miscarriage when expulsion takes place after the formation of the placenta but before the 28th week; stillbirth for expulsion of a dead fœtus after the 28th week.

[2] Falkiner, N. M. Clinical Reports of R[illegible]

Treatment.—The patient is given general advice on enatal care. One vitamin E tablet twice daily, one cium tablet thrice daily with milk, and iodised table t instead of ordinary table salt are prescribed. The ient is instructed to avoid excessive exercise, especially what would otherwise be her menstrual periods, and rest every afternoon in bed for two hours.

As routine antenatal care, at each weekly visit her ight is charted, her blood-pressure is estimated, her ne is tested for albumin and sugar, and she is given tisyphilitic treatment, consisting of ntramuscular oxyl 2 c.cm. weekly for eight weeks, followed by six eks' rest, continuously throughout pregnancy.

Contra-indications are recurrent toxæmia and fœtal ath due to blood-group difference (Rh factor).

COMMENT

The table shows that 54 patients had previously had 9 pregnancies but had produced therefrom only 55 e babies, which constituted a salvage-rate of only 22%. After antisyphilitic treatment these 54 patients proced from 54 pregnancies 49 live babies—a salvagete of about 90·7%.

Kahn reaction was negative in all cases. The Wassermann reaction was weakly positive in case 2, a trace positive in case 49, doubtful in case 5, and negative in the rest.

=arsenicals. Bi=bisoxyl. F.T.A.=full term, alive. Abor.=abortion. Mac.=macerated fœtus. Cæs.=cæsarean section (lower segment). * Ectopic pregnancy.

There were 4 cæsarean sections. This high rate is explained by the fact that these patients were treated primarily with the object of producing a live baby.

It is not suggested that the patients with a negative Wassermann or Kahn reaction were syphilitic; but the father may possibly have had syphilis partially treated, untreated, or fully treated.

SUMMARY

A history of habitual abortion, miscarriage, or stillbirth is often found in patients with no serological evidence of syphilis.

Good results can be achieved by treating these patients exactly as if they had syphilis.

Medical Societies

FAMILY PLANNING ASSOCIATION

ON Sept. 21 and 22 this association held in London a conference, under the chairmanship of Mr. A. S. PARKES, SC.D., F.R.S., on Infertility.

Rôle of Hyaluronidase in Fertilisation

Dr. G. I. M. SWYER recalled that the ovum of mammals, when freshly ovulated, was still surrounded by the cumulus, whose disintegration was an essential preliminary to fertilisation. McClean and Rowlands had demonstrated in 1942 that the enzyme hyaluronidase, whatever its source, was capable of denuding freshly ovulated rat ova. Rowlands in 1944 had suggested that the hyaluronidase in semen was derived from the spermatozoa, and that the sperms in an inseminate produced sufficient hyaluronidase to break up the cumulus rapidly and so permit penetration and fertilisation by one of their number. By adding hyaluronidase to diluted suspensions of rabbit spermatozoa, Rowlands had produced fertilisation with about a sixth of the minimum sperm concentration required in controls not receiving the added hyaluronidase; this suggested that the infertility of oligospermic semen might be due to an insufficiency of hyaluronidase. Dr. Swyer had developed an accurate viscosimetric method for the quantitative assay of hyaluronidase; and he showed figures proving a close statistical correlation between the sperm count and the hyaluronidase content in human semen. A similar relationship could be shown for the semen of other animals, although the absolute hyaluronidase content varied widely among different species. Calculations showed that the differences in hyaluronidase content in these species could account for the variation in the minimum sperm counts required for fertility. He described experiments in rabbits showing that up to 12 hours after mating or instilling hyaluronidase solutions into the vagina hyaluronidase could be recovered in washings from the lumen of the fallopian tube. He had also induced ovulation in female rabbits by an injection of gonadotrophin, which had been followed 7 hours later by an intravaginal injection of hyaluronidase; after a further 5 hours he had recovered denuded ova and had identified hyaluronidase in the tubal washings. From the fallopian tubes of control animals, given the gonadotrophin injection and distilled water per vaginam, ova within their cumuli and no hyaluronidase had been recovered. Trials were to be made on humans of the effect of hyaluronidase in sterility due to oligospermia. The hyaluronidase would be administered as a tablet or solution placed in the vagina before intercourse, or by addition to the husband's semen which would be artificially inseminated.

Antigenic Properties of Spermatozoa

The CHAIRMAN said that when spermatozoa were injected into an animal of a different species the recipient's blood was found to contain antibodies which could be demonstrated in vitro. The resulting antiserum reacted in high dilutions with spermatozoa of the species against which it had been raised, and in lower titres with the spermatozoa of other species. An antiserum prepared in a sheep against rat spermatozoa agglutinated in vitro the spermatozoa of the rat; less strongly those of the guineapig, rabbit, and dog; and slightly those of the human. It was difficult to show that antispermatozoal immune-bodies had any effect in vivo. For example, the passive immunisation of male guineapigs with large quantities of a potent antiserum prepared by injecting guineapig spermatozoa into a rabbit did not affect the condition of the epididymal spermatozoa, nor the production of spermatozoa by the guineapig testis. The evidence on the possibility of active iso-immunisation of an animal was conflicting. Positive results had been based mainly on complement-fixation tests. He himself, using as a criterion the in-vitro agglutination of spermatozoa, had consistently failed to find antibodies against rabbit spermatozoa after injecting rabbit spermatozoa into rabbits. Furthermore, this treatment had affected neither the sperm count and fertility of male rabbits nor the fertility of females. With vaginal insemination in female rabbits, a weak antibody response had sometimes been evoked, but only against heterologous spermatozoa, and less regularly than with injection by other routes. There was thus little experimental support for the theory that sterility in humans might result from injection of heterologous spermatozoa; and there was still less evidence of its production by natural or artificial insemination; among 13 women whose failure to bear children was inexplicable in terms of anatomy, physiology, or pathology the serum of only one showed a trace of antispermatozoal activity in vitro.

Artificial Insemination

Dr. **Margaret Hadley Jackson** and Mrs. **Clare Harvey** discussed their results with artificial insemination in infertility, using semen obtained from the husband, and compared the results with those where a donor's semen was used. Their cases had been carefully selected to exclude couples who appeared at all likely to produce children unaided; all the selected cases had been practising intercourse without contraception for at least two years. Artificial insemination with the husba semen was practised 165 times on 40 selected patient whom one received as many as 32 inseminations others only 1. There resulted only 2 pregnancies, one which terminated in a miscarriage and the other in a birth. Of these 40 women, 15 who were subfertile recei donor semen mixed with the husband's semen, and were finally treated with donor semen alone. All 15 husbands of this series had had repeated semen te of which 40 % were unsatisfactory in some, and 60-10 in the majority. From 41 inseminations with do semen mixed with the husband's semen there . only 2 pregnancies, of which one led to a live birth a the other to a miscarriage. Of the 5 women who recei donor semen alone (the total number of inseminatio being 27) none became pregnant. In 7 of these women pregnancy subsequently occurred as a result normal intercourse. In another series of 34 selected ca of infertility, artificial insemination with donor sem of high quality was performed on 254 occasions. The resulted 17 pregnancies, with 13 live births, 1 stillbir 1 miscarriage, and 2 which had not yet ended. Th concluded that artificial insemination with the husband semen did not yield good results, and that natur intercourse was more likely to be successful.

Habitual Abortion

Dr. **Raymond Cross** described the series which reported elsewhere in this issue. A lively discussio followed, in which the lack of controls in Dr. Cros experiment was criticised and the statistical significan of his results questioned. The dangers of using tox substances without urgent indications was stresse Other speakers claimed excellent results in the treatme of habitual abortion with simple measures, such as re in bed or even injections of distilled water.

Reviews of Books

Gynæcological Endocrinology for the Practitioner

P. M. F. **Bishop**, D.M. Oxfd, lecturer in applied physiology, Guy's Hospital. Edinburgh: E. and S. Livingstone. Pp. 124. 7*s*. 6*d*.

In this small useful book the endocrine control of the menstrual cycle is briefly discussed and the various sex hormones available for therapy and their methods of administration are set out. Dr. Bishop dismisses the natural œstrogens with the remark that they "have only one disadvantage—they are expensive"; and goes on to describe all treatment with œstrogens in terms of stilbœstrol. Many practitioners, however, still have a not entirely unfounded prejudice in favour of the natural œstrogens. He rightly stresses the dangers of continuous œstrogen therapy, and notes that very different doses are needed and can be tolerated in different physiological and pathological states: for instance, low dosage is needed during the menopause and high dosage during pregnancy. He mentions the uncertain results at present obtained with gonadotrophins, and gives a short account of pregnancy tests and hormone assays. Guterman's pregnanediol colour-reaction test might with advantage have been discussed; though its value and accuracy are not yet fully established, it promises to be clinically helpful both in detecting a tendency to abort and possibly in establishing the time of ovulation. Tables listing the various commercial products by name and giving their dosages and current prices are convenient. Dr. Bishop has remained nicely detached and free of dangerous enthusiasms, and has packed a great deal into small space.

The Nervous Child

(5th ed.) **Hector Charles Cameron**, M.D. Camb., F.R.C.P., consulting physician to the children's department, Guy's Hospital. London: Oxford University Press. Pp. 252. 10*s*. 6*d*.

In this book, first published in 1919 when child psychiatry in Great Britain was in its infancy, much of the original writing remains; and since it was based upon clinical observation of the behaviour of nervous children, and the attitude of their parents and nurses towards them, it has stood the test of time. Not only in the chapter on disturbances of metabolism but throughout the book, the psychosomatic conception illness and the interplay of mind and body in child healt are well portrayed. Sound advice is offered on th healthy upbringing of children and on the managemen of nervous symptoms. New material includes addition to the sections on enuresis, on night terrors, and o habitual vomiting of infancy. Both the plea to th psychiatrist in his dealings with children "to remembe how often the nervous disturbance is erected upon physical basis," and the statement that "the hygien of the child's mind is as important as the hygiene of hi body, and both are studies proper for the doctor" ar timely. The book is intended primarily for the guidanc of the medical practitioner, but can be recommende to any who are concerned in the practice of chil health.

Surgical Nursing and After-treatment

(9th ed.) H. C. **Rutherford Darling**, M.D., M.S. Lond F.R.C.S., surgeon, Prince Henry Hospital, Sydne London: J. and A. Churchill. Pp. 604. 12*s*. 6*d*.

For some 29 years this book has filled an importan place in the teaching of the nursing profession. M Darling has been thorough—keen to embody every littl advance, every little change or trick, in the passin years. But as Schiller observed "an artist may be know rather by what he omits." The tired nurse, working fo examinations in her spare time, must have the cro winnowed for her: she does not need to know abou "cardiac energy" or the "shock" index, about old fashioned Kimpton tubes or paraffined methods fo blood-transfusion, or even about somebody's pet metho of packing the rectum. What nurse sees a Phelp's bo used, or a petticoat tube for secondary hæmorrhage, o a Bavarian or Delbet splint? If the doctor likes t order some particular old-fashioned method, let hi explain to her how to use it. The book is too full for th present State course: the 700 pages make it longe than the shorter surgery textbooks for medical students The nurse's mind is no sponge, and there are limits t the amount that she should be expected to absorb i her scanty studying time. It would be far better t concentrate on selected details of the management of th cases she usually encounters: and in fact the book does give a good account of postoperative diet and othe nursing points. It has real merits, but it does not show the nurse the way through the wo

CORONARY CIRCULATION

Clinical experience indicates that theophylline-ethylenediamine may be a useful adjunct to the routine treatment of coronary insufficiency and for decreasing the frequency and severity of anginal attacks

An acceptable Stimulant

For debilitated patients and during convalescence, Tintara meets the difficulty of prescribing a stimulant that is both effective and readily taken. The fine flavour of this Australian Burgundy makes it acceptable to the most delicate. Produced from grapes grown on ferruginous soil, Tintara contains no added alcohol or sugar. It is a well balanced wine of minimum acidity and is entirely free from drugs.

Every effort will be made to supply Tintara when urgently required

Burgoyne's TINTARA
BURGUNDY

P. B. BURGOYNE & CO. LTD., DOWGATE HILL, LONDON, E.C.4 *Phone City 1616*

Stimulus to Intestinal Peristalsis

I-SO-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk, through absorption of water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetes.

It is valuable also in mucous colitis, dysentery, hæmorrhoids, and intestinal flatulence. After the performance of colostomy, I-so-gel gives excellent results by solidifying the fæces.

In bottles at 3/4 and 11/8½ each, including Purchase Tax.

The Small Ones

The Act provides that on the appointed day all voluntary and public-authority hospitals shall be transferred to the Minister of Health, except those he does not require for the National Health Service. Just what does this mean? The definition of a voluntary hospital is very wide, including as it does "any institution for the reception and treatment of persons suffering from illness" which is "not carried on for profit," and it thus comprises a variety of institutions ranging from the big general hospital to the small holiday-home which completes the treatment of the sick by giving them a holiday at the seaside. Between these extremes come a large (though unknown) number of small establishments, of which there is as yet no central record Most of these are homes either for the convalescent or for the chronic sick. Generally they are self-owned, and many of the people who manage them are still unaware that the National Health Service Act has any bearing on their activities.

What will be the best way of dealing with this mass of minor institutions? Unlike the hospitals they have no expensive apparatus and technical staff, and their chief asset is the devotion to the sick which inspires their management. This is a more delicate flower to preserve than the technical attributes of the big hospitals, but it is very well worth preserving. There is grave risk of its withering and fading under detailed control, and it seems to us that the intervention of authority should here be kept to a minimum. Where, as in hospitals, medical excellence is the main criterion, there is need of enough central influence to ensure the full use of scientific resources; but lower in the institutional scale, as technical efficiency grows less important and human relationships—"atmosphere"—more important, the advantages to be expected from such influence decrease. The smaller institutions intended for rest and recuperation will, we imagine, require control only so far as the safeguarding of public funds s essential, and may otherwise be left to themselves with only such distant supervision as an occasional official visit affords. A travelling accountant and visits from time to time by official visitors (both medical and lay) would be enough to ensure that proper standards are kept up, leaving the institutions themselves to build up their own particular methods of keeping the patients happy and contented. For this is the essence of the treatment which most of these homes exist to provide. Many of them, at least, are intended for patients who have done with medicine and now need only the natural stimulants—fresh air, exercise, good food, and pleasant occupation—to restore them to the state of health necessary for facing their daily work and troubles.

Whether or not it takes them over, the State will become responsible to some extent for these places, if only because their demise would throw their work back on the State itself. Cannot the maternal genius of unselfish people be left to preside over them, while the Ministry contents itself with the fatherly duties of watching over the little ones and paying the bills?

Streptomycin in Non-tuberculous Infections

STREPTOMYCIN, which was introduced by SCHATZ, BUGIE, and WAKSMAN[1] in January, 1944, as likely to be valuable in a variety of infections, is still known at second hand only to most doctors in this country, and it has been heralded chiefly as a potential weapon in the conquest of tuberculosis. But American reports make it clear that its proper assessment in tuberculosis will take a long time. Meanwhile evidence of its benefits in other conditions is accumulating, and a committee of the National Research Council[2] has lately reported on its use in 1000 miscellaneous cases.

Originally streptomycin was measured in terms of its activity against *Bact. coli*, but since the hydrochloride and sulphate salts have become available a microgramme of the pure streptomycin salt has been taken as equivalent to one unit; a gramme of the pure substance is then equal to 1,000,000 units. The streptomycin salt is a light yellow powder, usually supplied in ampoules. It is very soluble in water, and comparatively thermostable, though over long periods it is desirable to store it in a refrigerator. It is most commonly given by intermittent intramuscular injection. Intravenous administration produces a much higher initial concentration in the blood-stream, but after about 2 hours the blood-level falls below that attained by the intramuscular injection of an equal quantity. With ordinary dosage by either route traces of the drug can still be found in the serum after 10–12 hours. Injection into the muscle is painful at the time and for 24–48 hours afterwards, and a persistent ache may be felt at the site of repeated injections. The addition of procaine minimises the initial discomfort. The drug has sometimes been given in dilute solution by intravenous drip, but this route is generally undesirable because of possible toxicity, either of the drug or its impurities. It is not significantly absorbed by mouth, and this route is used only when the intention is to reduce the bacterial content of the intestines. Absorption from the respiratory tract after inhalation is also negligible. After parenteral administration it reaches peritoneal, pleural, and intraocular fluids, but not collections of pus, such as in empyemata It also appears in the bile, and in the fœtal circulation and amniotic fluid. Normally the concentration reached in the cerebrospinal fluid after systemic injection is low, but there is some evidence[3] that a much higher concentration develops in meningitis. Nevertheless it is usually given intrathecally as well as systemically in meningitis; and indeed into pleural and peritoneal cavities also, when local infections make it desirable.

Dosage varies widely, and attempts are made to relate the blood-level to the sensitivity of the organism concerned. In general 2–4 g. is given daily intramuscularly, usually 4-hourly. Intrathecally, 25–100 mg. in 5–10 c.cm. of saline once in 24 hours is suffi-

cient. For oral use 2–3 g. per day, given at 6-hourly intervals, is required Excretion is mostly by the kidney, and 60–80% of the dosage is normally found in the urine within 24 hours of administration. Therapeutic levels in the urine are therefore easily obtained. Many factors relating to dosage are still *imperfectly understood* For example, several investigators have reported a rapid increase in resistance to streptomycin in vivo, and WELCH and colleagues [4] have found experimentally in mice infected with typhoid that certain concentrations of streptomycin injected intraperitoneally actually increase the fatality-rate. The tolerance of bacteria to the drug may be increased four to eight times in the presence of blood or serum. A patient often varies in his rate of absorption, distribution, and excretion: and it is always uncertain that two patients with the same infection will react alike. Assessment of sensitivity of an organism in vitro often seems to bear little relation to the clinical response to what ought theoretically to be adequate dosage. It is not surprising that the duration of treatment required is also very variable: in general it is from 5 to 14 days.

Judging by the results of the American investigators in their 1000 cases, highly satisfactory results may be looked for in various kinds of gram-negative meningitis and septicæmia, if treated early, in tularæmia, and to a rather less extent in urinary-tract infections. In the treatment of meningitis they agree with CAIRNS and colleagues [5] that when treatment is delayed there is little prospect of benefit. Limiting factors in urinary infections include the presence of mixed organisms, irremovable local lesions, variations in sensitivity of organisms, and sometimes the development of extremely rapid resistance in vivo. The results in typhoid, salmonella infections, and brucellosis are disappointing—"no dramatic results have been observed in any of these infections." In pulmonary infections with Friedländer's bacillus or *H. influenzæ*, and in peritonitis from gram-negative infection, the results are difficult to assess but sufficiently encouraging to justify further extensive trials. Much work has also been done with experimental disease in animals; syphilis in rabbits and plague in mice have both proved susceptible to streptomycin, though in syphilis it is much less effective than penicillin. One report of success in experimental brucellosis in guineapigs [6] is unfortunately not paralleled in man.

Toxic reactions to streptomycin are comparatively frequent, the overall incidence in the National Research Council's 1000 cases being 20%. Headache, flushing, fever, and vertigo are among the commonest complaints, apart from local pain and irritation at the site of injection. Skin rashes are also common, developing mostly during treatment. They are erythematous, urticarial, maculopapular, or even hæmorrhagic in type, and may persist for a week or longer. If treatment is continued after the appearance of a rash much care is required, as other signs of sensitisation may appear. Neurological effects are the most disturbing of the toxic manifestations, although they tend to develop late and with lar doses only. BROWN and HINSHAW [7] report th caloric stimulation and turning tests show gradu impairment of labyrinthine function during strept mycin therapy, and that deafness and tinnitus m result from a toxic action on the cochlear apparatu The disturbance of equilibrium may be permanen but may be relieved by the development of com pensatory balancing mechanisms. Deafness tends recover with cessation of treatment, and may in som cases be the result of the primary disease. T incidence of toxic reactions begins to rise sharp when a daily dose of 1 g. is reached, and wh the daily dose is 4 g. or more the inciden reaches 60%.

The groundwork of investigation has been succes fully planned and put into effect in America, b there is much to be done before we know as muc about streptomycin as about penicillin. Distributi of supplies in this country is likely to follow t pattern cut for penicillin—a gradual widening availability as more of the drug is made and knowledge becomes precise enough to ensure th supplies are not wasted. Meanwhile streptomycin bound to be exceedingly scarce. In Berlin toda some relief from the shortage of penicillin is bei sought in the extraction of the drug from the urine patients who have received it. This was done here al in the early days, and it was then remarked th passage through the body removed impurities respo sible for febrile reactions. The evidence that 60–80 or even more of the total dose of streptomycin may excreted in the urine prompts the suggestion th methods of urinary extraction should again be explore

"I Was There"

THE campaign in Burma, so well described in th official account,[1] taught several medical lessons more than temporary value, both in epidemiolog and in the treatment of traumatic injury. Excep for the war in the Gran Chaco no major campaign modern times has been fought in the tropics, and th application of the lessons learnt in temperate and su tropical climates raised several interesting point Heat-stroke, inseparable from the deserts of the su tropics, was seldom seen; an annual rainfall 200 inches concentrated into three months was n bar to active warfare; snake-bite was little mo than an old wives' tale. The proportion of infecte wounds was very high but gas-gangrene was rar the streptococcus was an uncommon infecting age but the staphylococcus replaced it only too efficientl The major problem of the surgeon was evacuatio and in the early campaigns in the Arakan it wa necessary to move the wounded man, from ambulanc to ferry to ambulance to train, twenty-one tim before he reached a general hospital Air transpor for casualties had been used before, but never had it effects, on surgery and on morale, been so strikin as in 1945. A soldier wounded by the Irrawadd might be flown out in a light aeroplane from a 200 yard strip cut in the jungle. Within a few minute he was in a C.C.S., located at a strip long and fir enough to take a Dakota air ambulance. The sam evening he was in bed in a general hospital in Comilla 500 miles away. The system had a flexibility that allowed for almost any peculiarities of weather or terrain, and established welcome liaison between the line and the base. The consulting surgeon was as likely to be found at a main dressing-station as in his office.

[1] The Campaign in Burma. H.M. Stationery Office. Pp. 175.

Infectious diseases were prevalent enough, but, with one exception, they were those common to other theatres of war. Malaria, as always, had local peculiarities which had to be learnt before it could be overcome. Mepacrine, administered under strict discipline, had by 1945 reduced this menace to insignificance, and the Australians in New Guinea showed that the incidence might have been even lower. The war ended too soon for 'Paludrine' to receive a field trial. Dysentery of both kinds was, as in most theatres, the most distressing and intractable of camp-followers, and the gradual lowering of its incidence reflects great credit on the "hygiene wallahs" The syndrome of anæmia, lethargy, and diarrhœa, which came to be known as "para-sprue," remained an unsolved problem to the end. Infectious jaundice was as common as elsewhere. The only disease of which few had had experience and which might have been a problem of the first magnitude was scrub-typhus. This was never conquered, but enough was learnt of its natural history to make its incidence trivial among the other hazards. A comparison of the health of captured Japanese with that of our own troops was a great testimonial to preventive medicine and the value of the various research teams associated with the Allied forces.

Where the war in Burma differed radically from all others was in the revolution in the supply services. General WINGATE had suggested sending stores "down the chimney, like Father Christmas," and that was done. It was an inspiring sight to see the aeroplanes leaving Hathazari loaded with everything which the Army might need, down to the daily newspaper, *S.E.A.C.*, whose editor has written the official account. Bandages, splints, mepacrine, and penicillin went up in the aeroplanes that brought the wounded back.

Of morale it is hard to speak. Military circles will continue to argue the value of the airborne penetrations by the Chindit columns, but no-one has yet found praise enough for the men who made them. It is perhaps characteristic of the morale in Burma that WINGATE'S last message—"One day you will be proud to say 'I was there'"—became the nickname of a species of hat[2] not recognised in the dress regulations of the Indian Army.

PERSPECTIVE

"HAS anybody heard any good news lately?" Mr. Donald McCulloch put this question to last week's Brains Trust; and there was silence. To the British people good news would be a welcome tonic, for things are not as most had thought to find them nearly eighteen months after the end of the war. Measuring our present utilitarian habits against the distant pre-war life by its chances for variety in food and scene and clothing and a hundred other intrinsically unimportant items, we see that the old standard is still far beyond reach. In the wider sphere, too, those who spoke of, and believed in, the moulding of a better world as the first task to which the nations should turn their hands now find such talk strangely hollow against a background of international bickering. Yet these disappointments have given rise to no spirited questioning and to no incisive call to action; for we are touched with the same malaise as after the first world war—a fatigue of which we were largely unaware during the struggle itself.

If, in surrender to this exhaustion, we are indifferent to our own affairs, we are perhaps doubly careless of others'. Hungry Germany is a case in point, though here there is the excuse that tales of famine have so long been part of the daily news that they no longer carry their former impact of shock and urgency; as with the war-time casualty lists, the implications of the printed word are obscured by constant repetition. Moreover, though there is general want, there is not yet stark famine in Germany; subsisting on a basic ration that has wavered from about 1500 to under 1000 calories, the western German still lives in the narrow borderland that divides malnutrition from frank starvation. The newspapers, on which we largely rely for our knowledge and judgment of human events, though they have conscientiously reported this state, have been hindered in giving it full weight by the poor news-value of the subject. Fires and murders, battles and burglaries—these, having beginning, incident, and climax, lend themselves to graphic description. Famine or near-famine has no such definite phases; its drama is reserved for those who see and those who suffer; the plot varies little from Monday to Friday, or from Cologne to Chungking; and its dénouement in swollen numbers of sick and dead make chilly reading.

Nowadays even the sober accounts which come out of Germany are often suspect. Were there not for nearly four years stories of terrible want in western Europe, which were ended only when the liberating armies found that, except in Holland and a few towns elsewhere, conditions had almost all along been tolerable? Some recall the Germans' buxom health in the early days of occupation, their well-stocked larders, and their weekly trips to the country from which they returned laden with produce. Having been the best-fed people in Europe for five years, so the argument runs, they can now best afford to starve; and anyhow the official ration is not the only regular source of food. These contentions take no regard of the fact that the initial advantage was lost last winter; and that since then the country folk have had no further surplus for the town-dwellers who form the bulk of the British zone's population. For all except the lucky few who have the money to buy in the black market the official ration is now the total ration. The final argument is that the German people alone are answerable for their present predicament. Even this is hardly correct, for we assumed the reins of government and thus, by implication, responsibility for the people we govern; it is we who, by agreement with the other occupying powers, have divided the country into discrete sections so that there has been no free exchange of manufactured goods from the urban west for food from the rural east; and it is we who, following the Potsdam agreement, have so reduced the economic strength of our zone as to cripple its purchasing power. "Eighteen months after the surrender," writes an *Observer* correspondent,[1] "the German inhabitant of the British zone faces a second winter of hunger and cold without the stocks of food, fuel, and clothing he had a year ago, weakened by six months of starvation-rations, and with a feeling of utter hopelessness, despair, and bitterness."

PENICILLIN IN ACUTE NEPHRITIS

THE generally accepted view of the lesion in acute glomerulonephritis—Ellis's type 1 nephritis—does not encourage the hope that the condition would be benefited by sulphonamides or penicillin. The sulphonamides, despite enthusiastic early reports, have in fact provided no substantial advantage, and their toxic effects are often serious. The freedom of penicillin from this disability, and the clinical impressions of benefit, such as that recorded by Moncrieff,[1] together with the observed relationship of infection to nephritis, call for further investigation of its effect. From experience with 25 cases, 10 of them afebrile, Sen [2] concludes that in children with febrile conditions associated with nephritis penicillin may minimise the illness by dealing with the focus of infection. Furthermore, even in afebrile cases he has noted a rapid increase in urinary output, and general clinical improvement; and he suggests that penicillin has a direct influence on the kidney itself, whereby the illness is shortened. Unfortunately he has not been able to observe a control series, and the information he gives about the original infection and the clinical condition is incomplete. At present the claim must be regarded as unproved, but a carefully controlled assessment is clearly desirable.

BRITISH NATIONAL HEALTH INSURANCE

THOUGH compulsory insurance against sickness and accident was instituted in this country on a national scale at so comparatively recent a date as 1911, voluntary health insurance had by that time been operating for several centuries. The social guilds of the Middle Ages, whose records, collected in 1388–89, may be studied in the Public Record Office in London, provided cash benefits to their members in time of sickness; and after the guilds had been suppressed by Henry VIII new agents of voluntary health insurance appeared in the friendly societies. Some steps had even been taken towards compulsory health insurance. In 1697 a scheme of health insurance on a compulsory basis was published by Daniel Defoe; and in 1786 the Rev. John Acland, rector of Broad Clyst, Devon, worked out a scheme of compulsory health insurance, which, embodied in a Bill, was introduced into the House of Commons in 1787 but failed to secure a second reading. In 1757 a statutory obligation to insure against sickness was imposed on coal-heavers working on the Thames, and in 1792 a similar scheme was applied in the coal trade on the Wear.

Prince Bismarck was the first to cause a national scheme of compulsory health insurance to be enacted, though local schemes had then been long in operation in Germany. His scheme, which, it was said, was introduced to trump the long suit of the Social Democratic Party, became law on May 31, 1883, and came into operation on Dec. 1, 1884. In 1909 it was studied on the spot by Mr. Lloyd George, who, in his Budget speech of that year, spoke of it in glowing terms:

> "And a superb scheme it is. It has saved an incalculable amount of human misery to hundreds of thousands and possibly millions of people who never deserved it. Wherever I went in Germany . . . men of all ranks, sections, and creeds of one accord joined in lauding the benefits which have been conferred upon Germany by this beneficent policy."

Mr. Lloyd George added that the Government intended to bring in a scheme of national health insurance. It was brought in as part of the National Insurance Bill, which, introduced into the House of Commons on May 4, 1911, and, drastically amended to meet the criticisms of the medical profession, received the royal assent on Dec. 16, 1911.

The scheme as presented to Parliament was based
the German model, and contained provisions to wh
the medical profession strongly objected. At the in
tence of the British Medical Association many ame
ments were made, the most important of which we
(1) the administration of medical benefit was transfer
from the approved societies to specially created insura
committees containing representatives of the medi
profession ; (2) all registered medical practitioners w
given the statutory right to have their names plac
on the list of doctors undertaking the medical care
insured persons ; (3) insured persons were given
statutory right to choose, and change, their insura
doctors subject to acceptance by the doctor ; (4)
every insurance-committee area a local medical co
mittee was to be formed, recognised by the Governm
as representing the medical profession of the area, a
charged with certain important administrative functio
As a result of these provisions, which embodied princip
for which the German doctors had long been contendi
the medical profession has coöperated with the Gove
ment in the administration of the British system, wh
operation has been free from the embittered *disput*
between the profession and the administrative authoriti
that had been not uncommon in Germany. The B.M.A
in their evidence submitted to the Royal Commissi
on National Health Insurance, not only recommend
the continuance of the health-insurance system b
urged that it should be extended to include the depe
dants of insured persons and to provide a wider ran
of service. The royal commission, reporting in 192
recommended that such extensions should be ma
"as and when opportunity offers and funds beco
available" ; but, being impressed with the difficul
of retaining the insurance principle in a service of wid
scope, added :—"The ultimate solution will lie, we thin
in the direction of divorcing the medical service entire
from the insurance system and recognising it along wi
all the other public health activities as a service to
supported from the general public funds."

The change foreseen by the royal commission is no
on the eve of accomplishment. The Insurance Medic
Service, as a separate service, will soon be a thing of t
past ; it will be merged in a complete National Medic
Service. The British health-insurance system is unde
going a profound change. A new period in its histo
is opening, and the time is propitious for a comprehensi
review of the system—a review that should include
account of the sources from which it sprang and of i
actual working and development, and an appraisal
the measure of success it has achieved. Mr. R.
Harris has presented such a review in his book *Nation*
Health Insurance in Great Britain 1911–46,[1] which w
be found very useful by students of health insuranc
whether in this country or abroad. Mr. Harris h
unique qualifications for writing on the subject. As
civil servant he was associated with the late Mr. W.
Braithwaite in helping Mr. Lloyd George to steer t
National Insurance Bill through Parliament, a tas
involving preparations for the reception of innumerab
deputations and the answering of innumerable inquiri
He was one of the first-appointed members of the sta
of the English Health Insurance Commission, and becam
an assistant secretary in the Ministry of Health ; an

a way that throws light on present difficulties and ntroversies. There are, however, some curious omis- ons; including the lack of an index. No reference is ade to Henry Ratcliffe, who was the first to place iendly-society finance on a sound actuarial basis, or to r Robert Morant, without whose administrative genius id immense driving power the health-insurance system uld hardly have got under way in the short seven onths allotted for the purpose.

HOW LONG DEAD?

The scientific aids towards identifying a person found ad have increased enormously in number and efficiency the last few decades, but Simpson[1] shows that they ve not made easier the job of assessing the time of ath. X rays, blood-groups, dentition, estimation of ight from a small piece of limb bone—all these are valuable in deciding on the victim's identity, but tell s nothing about the hour of death. Simpson holds that e most reliable guide is the steady fall in temperature hich takes place up to twenty-four hours after death. nder average conditions about 2·5° F is lost each hour r the first six hours, and 1·5°–2° F for each of the next x hours. Calculations based on these figures may be pelessly upset by extremes of temperature, the amount clothing the man was wearing, ventilation, and vironment—thus a body in a river will reach the mperature of the surrounding atmosphere much more ickly than one on dry land. If parasites, such as fleas r body lice, are present, the entomologist may help by ding out whether these creatures are still alive, and, so, how long it takes to revive them. Adipocere may nder rather than help, for the hydrogenation of body t is notoriously variable; it may take place in three four weeks (with warmth), or may be delayed well yond the four to five months which is the average r this country. The onset of rigor mortis and of post-ortem staining are of little use in placing the time of ath accurately. All in all, Simpson seems to place ost reliance on body temperature. "It is never too te," he says, "to measure the temperature in the hope at, though 'the body is cold,' it may still register a w degrees above that of the surroundings." He quotes an example a murder at Hastings where the body mperature was still 7° F above air temperature, after ghteen hours in the snow, and this made it possible to x the time of death within an hour.

VARIOUS OPINIONS ON B C G.

Several months ago the Ministry of Health received om bodies interested in the prevention of tuberculosis memorandum recommending the supply and use of C.G. in this country[1]; and the Minister has lately nounced that B.C.G. is to be manufactured in this untry. This may make it possible to undertake the ntrolled investigation for which workers here have ped, and it will be well to take account of some of e pitfalls and possible disappointments indicated by recent report from America. Leviné and Sackett[2] ccinated with B.C.G. a series of young children from berculous families in New York City. No child above e age of one month was accepted unless the tuberculin st and radiological and clinical examinations were gative; with parenteral vaccination, 85% became berculin-positive. At first an attempt was made control the study by dividing the children into two qual groups—those to be vaccinated and those to be sed as controls—a physician being assigned to vaccinate alf the cases; and between 1927 and 1933 altogether 90 children were studied in this way. The results were npressive, for there were only 3 deaths from tuberculosis amongst the vaccinated compared with 18 among the controls; in other words the number of deaths from tuberculosis was four times greater (3·38%) in the control group than in the vaccinated group (0·68%). Experience showed, however, that selection was taking place; there was a tendency to inoculate the children of the more intelligent and coöperative parents and to keep the children of the uncoöperative parents as controls.

From 1933 onwards alternate children were vaccinated, the selection being made before they were assigned to pædiatricians. Since some children had to be withdrawn from the investigation, the number of controls and vaccinated differed. Altogether 1094 children were studied, of whom 566 were vaccinated (all intracutaneously with 0·15 mg. B.C.G.) and 528 were controls. The tuberculosis deaths among the vaccinated were 8 (1·41%) and among the unvaccinated controls also 8 (1·51%). The possible effects of parental coöperation, economic conditions, racial distribution, exposure, lost cases, and percentage of autopsies were all assessed, but without the discovery of any factor vitiating the comparison. It was found that, among the children segregated in hospital for three months before and three months after vaccination, there were among the 91 vaccinated 1 death, and among the 96 controls 3 deaths, from tuberculosis; in the former group the child who died, though born of a mother who died of tuberculosis, was never exposed, whilst in the latter group one child who died had not been exposed as far as was known. Levine and Sackett regard it as dangerous to take children into hospital during the first three months of life; but they consider that, when a child is admitted, B.C.G. may have some protective value. They conclude that B.C.G. must be judged by the results in children vaccinated at home; and as a public-health measure they rate it below removal of the tuberculous subject from the home.

The Scandinavian countries, on the other hand, from long experience have no doubt of the value of B.C.G., which is being increasingly used. In Denmark, for example, the number of vaccinations has crept up from 82 in 1934 to 40,000 in each of the last two years. The tuberculosis dispensaries are being overwhelmed by this extra work; and at a recent meeting of the Danish Association of Tuberculosis Doctors[3] it was suggested that general practitioners, whose interest has hitherto been lukewarm, should be offered courses of instruction so as to win their active participation. While the administration of the vaccine seems to be plain sailing, its production demands constant skill and attention. Dr. K. A. Jensen, who has been culturing the strain since 1927, has found considerable difficulty in keeping it on the narrow path of therapeutic rectitude. "The ideal," he said, "is never reached. The man who is to cultivate the B.C.G. strain and keep it at a level of suitable virulence has a very responsible post. If the virulence falls, so will the percentage of persons becoming tuberculin-positive after vaccination . . . if the strain become too virulent, the number of complications will rise. Both events would be equally unfortunate, since each would bring B.C.G. into disrepute." In Denmark the vaccine has been cultivated on Sauton medium, with subcultivation about every two weeks.[4] The slow loss of virulence after repeated subcultivation was formerly corrected by several passages on bile-potato medium; but of late years the same effect has been obtained by more frequent transfers on the Sauton medium (every 7–10 days), thus corroborating experimental evidence that virulence depends essentially on the rate of growth on Sauton medium. Dr. Holm,[4] who heads the tuberculosis division of the State Serum Institute, is satisfied with the absolute safety of the vaccine. Its use is

now being extended beyond those particularly at risk to others, including all tuberculin-negative soldiers in the Danish army; and the present trend is towards the vaccination of all school-children. This year a tuberculosis survey has been initiated for the population of Copenhagen, to include tuberculin-testing and vaccination of all the tuberculin-negative aged 15–35 years.

DOSAGE OF CURARE

THERE are now on the market two preparations of curare for use in anæsthesia, one amorphous and one crystalline; both depend for their activity on *d*-tubocurarine chloride but they differ in potency, the amorphous preparation 'Intocostrin' having about a quarter of the activity of the pure crystalline material. This difference is a source of danger and might result in serious accidents. There is also some evidence of wide variations in individual reactions, depending to some extent on the patient's state of health. Thus in one otherwise healthy man with a recent perforated gastric ulcer as little as 5 mg. of the crystalline material produced adequate muscular relaxation, and 15 mg. would probably have been a considerable overdose. The anæsthetics committee,[1] jointly appointed by the Medical Research Council and the Royal Society of Medicine, are considering the standardisation of curare. Meanwhile they recommend that dosage should be based on the individual reaction to an initial small injection rather than on any dose/weight ratio. In the average healthy adult this initial dose could be 10–15 mg. of crystalline *d*-tubocurarine chloride or 40–60 mg. of intocostrin.

ADVERTISEMENT OF PROPRIETARY MEDICINES

LAST Monday the Hunterian Society met at Apothecaries' Hall, under the chairmanship of their president, Dr. J. B. Cook, to debate: That the Advertisement of Patent Medicines is a Menace to the Public. Mr. Hugh Linstead, M.P., speaking for the motion, admitted that the busy practitioner would be in difficulties if everyone had to come to a doctor for simple remedies. There had been great improvements in the materials and the advertisement of proprietary medicines since the Royal Commission of 1914. Nevertheless, much remained to be done. Advertisers obeyed the letter rather than the spirit of regulations; mention of "cure" was prohibited by newspapers, but "abolish," "kill," and other terms suggesting cure still appeared. There was still no control over postal advertising. There were too many worthless medicines on the market; prices were excessive; the disclosure demand was too often made the occasion for concealment; scientific terms were misused to mislead the ignorant; and advertisers played on fear. The Ministry of Health should shoulder the task of control as in Canada, where there was prohibition of the sale of proprietary medicines associated with claims for cure, or for which false, misleading, or exaggerated claims were advanced.

Dr. G. H. D. Day could not recall a single instance in which use of these medicines had delayed recourse to medical attention. The patent-medicine addict was the frustrated doctor-addict. These medicines did at least renew hope; and "an act of faith can alleviate symptoms, restore function, arrest disease, and promote healing." The sick man wanted a bit of magic. There existed in the patient a deep sense of the need for sacrifice. There was, too, an ineradicable impression that if the best was to be obtained it must be paid for. When the panel system came in the sale of patent medicines had soared; it would now again increase, because this was the only remaining altar on which to make a sacrifice. Notwithstanding all this, Dr. Day opposed their advertis for this had an element of duality. In childhood, were projected on to the bogyman; now these to be transferred to halitosis and B.O. Patients willing to accept this as punishment for their g feelings. "What have I done to deserve this?" often heard. Advertisements suggested that ill he was the common lot; and the sales depended on creation of ill health. The outrageous cost could forgiven, for it offered a chance for expiatory sacrif but the advertisements could not be forgiven, because increased the storehouse of anxiety and unhappiness

Mr. Arthur Mortimer, a director of the Beecham Gr opposing the motion, admitted that a few propriet medicine manufacturers work under reprehensible co tions; the reputable section of the trade would lik stop this. The difficulty in the control of advertisem was that the railways permitted advertisements w the newspapers refused. Any exaggeration was sin "puff" by manufacturers justly proud of their prod And was it right to stop all advertisement because a exaggerated? So long as the proprietary-medicine tr was rendering service—and there was nothing wrong w most of it—it should be allowed to advertise. industry would welcome legislation on the lines accep by Canada if it was going to help.

Mr. J. S. Walmsley, secretary of the Propriet Association, insisted that proprietary-medicine adverti was informative rather than persuasive. The valu advertising was in its results; no manufacturer c afford to advertise unless his product benefited patient. The advertisement of proprietary medic was more closely controlled than any other form advertising; and the quality of advertising had impro enormously since 1939.

In other speeches it was suggested that the pre conciliatory attitude of the trade is due to the ma facturers having seen the red light. A large majo supported the motion.

MEALS AND THE ELECTROCARDIOGRAM

SURPRISINGLY little is known about the effects of f on the electrocardiogram. Simonson and his colleagu have now studied the findings in twelve healthy yo adults before and after standard mixed meals and high meals of 942–1548 calories. The significant change the limb leads were an increase of heart-rate; an incr of K_{QT} (i.e., $QT/\sqrt{R-R}$); a decrease of the T wa the Q–T interval, and the duration of mechanical syst and an increase of the amplitude of QRS. In the c leads the T wave became more positive in CF_1, whil CF_2 and CF_4 it was decreased. Frequent but inconst changes were noted in the P wave, while there was li change in the P–R and QRS intervals, the Q wave the S–T segment. These changes were noted half an h after the meal and were still present an hour after meal. The next question to be investigated is the ef of a meal on the abnormal electrocardiogram.

TWO STAGES?

TUESDAY'S *Times* contained a letter from Sir He Bashford, late medical adviser to the Treasury, suggest that the Government should postpone provision general-practitioner services under the new Act until hospital services are working satisfactorily—in perh five years' time. "Meanwhile let general and pa practice go on as before." From such a source t proposal commands attention; but it would be idle ignore the public dissatisfaction it would cause, and difficulties it might create in administration of the n insurance scheme and in resettlement of ex-Serv doctors.

CONFERENCE ON MENTAL HEALTH

SOME PROBLEMS OF TODAY

At its first meeting, with Prof. J. M. MACKINTOSH in the chair, the conference, held in London on Nov. 11 and 15 by the Provisional National Council for Mental Health, discussed how to apply to the civilian population war-time experience of neurosis and backwardness in the Forces.

The Lessons of War

Dr. J. R. REES (medical director, Tavistock Clinic) said that the recent war gave us an opportunity of confirming much that was learned in its 1914–18 predecessor: but if little that is completely new has been learned of the nature and treatment of acute war neuroses, there have been considerable advances in prophylactic psychiatry, and in team-work among psychologists and sociologists. Large groups of men and women under discipline, sharing a common purpose and selected to some extent before admission to the Services, can of course be more easily managed than the free and more heterogeneous group in industry and the general community; but experiments done in the Army have some bearing on civil life, and methods can be adapted to meet civilian problems. In the first place, many men and women with long histories of minor neurotic difficulty gave first-rate service in the Army, and some were healthier and fitter than they had been as civilians. Those who had never been able to adapt in civil life were clearly unlikely to adapt easily to the challenges presented by the Army. It is no light matter to be uprooted from home, business, and friends, and all familiar grooves, and to be placed in an almost exclusively masculine environment, without privacy, and with what seems the complete loss of a carefully built-up individuality. Separation from home was by far the most potent single predisposing factor in psychiatric wastage; and, by study of the personality problems associated with it, it should be possible to lay down standards which would apply to such things as population-shift in civil life.

Some 15% of all passing through the General Service Selection (established in 1942) were referred by the interviewing officers to Army psychiatrists, either because of low intelligence or because they seemed unstable. Since the other Services had prior choice, the Army took a considerable part of the "psychopathic tenth" of the population. Many neurotic men, by selection, were kept out of combat, where they would have broken down and injured the morale of others, and were given work at the base, on the lines of communication, and in units which were not likely to see much fighting. Many who had come in before selection started and who did break down were admitted to hospital and helped up to a point—there was no time to achieve "cure." Those who could not be returned to their own units on discharge were fitted into jobs in line with their civilian interests and skills; and this plan, time-absorbing as it was, paid a handsome dividend. A high proportion of them gave good and willing service without any further breakdown. They were not cured, but they were able to be and feel useful, and to remain stable.

Effects of selection were specially remarkable, he said, among mental defectives. The dull man holds up training, and realising his inferiority he becomes anxious, breaks down, possibly malingers. What little malingering there was in the Army was largely among dullards, and some 70% of occupants of military prisons were men below the median on the intelligence scale. Eventually many of the most backward men were employed solely on manual labour, and worked contentedly. With good officers and N.C.O.s they became smart and reliable, with lower sickness- and crime-rates than good units of the field force.

Selection of officers proved most fruitful. Intelligence, character, and personality were assessed with increasing certainty, and psychological testing and interviewing found good men who would not otherwise have been accepted. If we can choose good officers he thinks it likely that good directors of industry, good schoolmasters, and good doctors can be chosen with even greater success. Training, moreover, can be fitted to capacity. The Canadian Army successfully used three-speed training—for the below-average, the average, and the above-average groups. Finally, much was learned about group-structure and group-therapy which must have a civilian application.

Dr. G. R. HARGREAVES (chief medical officer, Unilever Ltd.) said that mental-health work is done best by a team; and the pattern of the Army team proved to be the same as that of the civilian child-guidance unit. The work was partly detective—a study of the neurosis when it had already been acquired; and partly preventive—an examination of the social setting of the illness. Dullness, he noted, is often a social rather than a clinical problem. The industrial revolution largely destroyed the village community with its mixture of classes: nowadays people live in concentration camps—in suburbs or in housing estates. The small mixed community has gone, and the only two groups to which most people belong are the family unit and the work unit. The only effective integrated group to which the working man belongs is to be found in his industry; and industry has the great opportunity of carrying over the lessons in mental health learned in the Forces.

Dr. F. J. S. ESHER (medical officer, Sheffield mental-welfare service) said that he had tried placing a group of dull people in appropriate jobs, and on interviewing some 30–40 later had found them happy and doing well. Some have married happily: many defective girls, he said, keep good homes and look after their children well.

Dr. REES, summing up this part of the discussion, remarked on the importance of collaboration between vocational-guidance centres and the people who knew what jobs are available.

EMPLOYMENT OF THE HANDICAPPED

Dr. T. F. MAIN (medical director, Cassel Hospital) recalled that low intelligence is not the only problem of the mentally handicapped: they must also face failure, perplexity, loneliness, and fear of competition in the industrial field. Reading and writing are difficult, which means failure to follow the news, confusion, and insecurity. Human relations are not easy, and the dullard may cling to his own poor kind and marry among them. Many find a pattern of life which suits them, doing humble blind-alley jobs; but they are often in money difficulties because even an intelligent person would find it hard to handle similar responsibilities on like wages. They need a counselling service to which they can turn for advice on housing, rents, clothing, food, maternity services, education, and health. Without it they are often timid, unhappy, inefficient, ailing, despairing, sullen, and delinquent, and sometimes criminal. If their handicap is severe they may be helped by colony life, or by the new opportunities under the Disabled Persons Act. But those with less obvious handicaps are not easily identified. They don't walk into outpatient departments complaining of limited capacities. However, difficulty in holding a job is common in their records; and free expert medical assessment and advice might be offered to any worker who has consistently shown slowness in learning or difficulty in holding jobs, even if the overt reason for unsettlement is ill health. Fear of stigmatising the mentally handicapped could be avoided if the same assessment were offered to workers in other difficulties—to those with poor vision, for example.

Many dullards are relieved to find someone who will discuss their handicap practically and without patronage; and if this can be coupled with practical measures to find them suitable work they are grateful. If the present chronic flirtation of the Ministry of Labour and the psychiatric services is to ripen into an organised engagement and a solid marriage, he said, these, their children, will enjoy being legitimised. They have a high potential value in industry because they can happily undertake work which would bore the intelligent—manual work of a simple repetitive kind in a stable industrial background is the kingdom of the dullard. They need help in the settling-in period, so that they get a sense of "belonging" to the job and their fellows.

The epileptic, the schizoid, the obsessional, the depressed, and the hysteric also need special help—a sheltered transitional period before they return to now being extended beyond those particularly at risk to others, including all tuberculin-negative soldiers in the Danish army; and the present trend is towards the vaccination of all school-children. This year a tuberculosis survey has been initiated for the population of Copenhagen, to include tuberculin-testing and vaccination of all the tuberculin-negative aged 15–35 years.

DOSAGE OF CURARE

THERE are now on the market two preparations of curare for use in anæsthesia, one amorphous and one crystalline; both depend for their activity on *d*-tubocurarine chloride but they differ in potency, the amorphous preparation 'Intocostrin' having about a quarter of the activity of the pure crystalline material. This difference is a source of danger and might result in serious accidents. There is also some evidence of wide variations in individual reactions, depending to some extent on the patient's state of health. Thus in one otherwise healthy man with a recent perforated gastric ulcer as little as 5 mg. of the crystalline material produced adequate muscular relaxation, and 15 mg. would probably have been a considerable overdose. The anæsthetics committee,[1] jointly appointed by the Medical Research Council and the Royal Society of Medicine, are considering the standardisation of curare. Meanwhile they recommend that dosage should be based on the individual reaction to an initial small injection rather than on any dose/weight ratio. In the average healthy adult this initial dose could be 10–15 mg. of crystalline *d*-tubocurarine chloride or 40–60 mg. of intocostrin.

ADVERTISEMENT OF PROPRIETARY MEDICINES

LAST Monday the Hunterian Society met at Apothecaries' Hall, under the chairmanship of their president, Dr. J. B. Cook, to debate: That the Advertisement of Patent Medicines is a Menace to the Public. Mr. Hugh Linstead, M.P., speaking for the motion, admitted that the busy practitioner would be in difficulties if everyone had to come to a doctor for simple remedies. There had been great improvements in the materials and the advertisement of proprietary medicines since the Royal Commission of 1914. Nevertheless, much remained to be done. Advertisers obeyed the letter rather than the spirit of regulations; mention of "cure" was prohibited by newspapers, but "abolish," "kill," and other terms suggesting cure still appeared. There was still no control over postal advertising. There were too many worthless medicines on the market; prices were excessive; the disclosure demand was too often made the occasion for concealment; scientific terms were misused to mislead the ignorant; and advertisers played on fear. The Ministry of Health should shoulder the task of control as in Canada, where there was prohibition of the sale of proprietary medicines associated with claims for cure, or for which false, misleading, or exaggerated claims were advanced.

Dr. G. H. D. Day could not recall a single instance in which use of these medicines had delayed recourse to medical attention. The patent-medicine addict was the frustrated doctor-addict. These medicines did at least renew hope; and "an act of faith can alleviate symptoms, restore function, arrest disease, and promote healing." The sick man wanted a bit of magic. There existed in the patient a deep sense of the need for sacrifice. There was, too, an ineradicable impression that if the best was to be obtained it must be paid for. When the panel system came in the sale of patent medicines had soared; it would now again increase, because this was the only remaining altar on which to make a sacrifice. Notwithstanding all this, Dr. Day opposed their advertisem for this had an element of duality. In childhood, were projected on to the bogyman; now these to be transferred to halitosis and B.O. Patients willing to accept this as punishment for their feelings. "What have I done to deserve this?" often heard. Advertisements suggested that ill h was the common lot; and the sales depended o creation of ill health. The outrageous cost coul forgiven, for it offered a chance for expiatory sacri but the advertisements could not be forgiven, because increased the storehouse of anxiety and unhappines

Mr. Arthur Mortimer, a director of the Beecham G opposing the motion, admitted that a few proprie medicine manufacturers work under reprehensible c tions; the reputable section of the trade would li stop this. The difficulty in the control of advertisen was that the railways permitted advertisements w the newspapers refused. Any exaggeration was si "puff" by manufacturers justly proud of their pro And was it right to stop all advertisement because a exaggerated? So long as the proprietary-medicine t was rendering service—and there was nothing wrong most of it—it should be allowed to advertise. industry would welcome legislation on the lines acce by Canada if it was going to help.

Mr. J. S. Walmsley, secretary of the Proprie Association, insisted that proprietary-medicine advert was informative rather than persuasive. The valu advertising was in its results; no manufacturer c afford to advertise unless his product benefited patient. The advertisement of proprietary medi was more closely controlled than any other for advertising; and the quality of advertising had impr enormously since 1939.

In other speeches it was suggested that the pr conciliatory attitude of the trade is due to the m facturers having seen the red light. A large maj supported the motion.

MEALS AND THE ELECTROCARDIOGRAM

SURPRISINGLY little is known about the effects of on the electrocardiogram. Simonson and his colleag have now studied the findings in twelve healthy y adults before and after standard mixed meals and hig meals of 942–1548 calories. The significant chang the limb leads were an increase of heart-rate; an inc of K_{QT} (i.e., $\text{QT}/\sqrt{\text{R–R}}$); a decrease of the T w the Q–T interval, and the duration of mechanical sys and an increase of the amplitude of QRS. In the leads the T wave became more positive in CF_1, whi CF_2 and CF_4 it was decreased. Frequent but incons changes were noted in the P wave, while there was change in the P–R and QRS intervals, the Q wav the S–T segment. These changes were noted half an after the meal and were still present an hour after meal. The next question to be investigated is the e of a meal on the abnormal electrocardiogram.

TWO STAGES?

TUESDAY's *Times* contained a letter from Sir H Bashford, late medical adviser to the Treasury, sugges that the Government should postpone provisio general-practitioner services under the new Act until hospital services are working satisfactorily—in perl five years' time. "Meanwhile let general and p practice go on as before." From such a source proposal commands attention; but it would be idl ignore the public dissatisfaction it would cause, and difficulties it might create in administration of the insurance scheme and in resettlement of ex-Ser doctors.

administrative agencies does not destroy the unity the health service as a whole; the patient has only to ow his need of assistance, and it is our privilege to give to him. Mr. Bevan believed we must have psychiatric ntres in our general hospitals, so that patients will ek help for mental illness as readily as they will for any ther kind. Aftercare and continued assistance are also sential, so that people get the right things to do in the ght sort of company. We have a social conscience owadays, and we must create a social machine to serve it.

The second day's discussions were largely concerned ith educational problems.

ROYAL COLLEGE OF SURGEONS

NATIONAL HEALTH SERVICE ACT

AT the annual meeting of fellows and members held on Nov. 13, Sir **ALFRED WEBB-JOHNSON**, the president, gave a brief address on the National Health Service Act. With regard to hospitals, he said, considerable concessions had been made: the State had taken over the hospitals, and a monopoly in hospital services was thus created, but concessions had been made in the direction of more freedom of control to the management. The provisions with regard to the appropriation of trust funds had also been modified to a considerable extent, and the funds would, as far as possible, be used solely for the benefit of the hospitals. Concerning specialist practice and the restrictions put upon doctors who were not in the public service, the college had fought for the principles expressed at its meetings. A confused and rather ill-informed debate on the matter had taken place in the House of Lords, and he read a correspondence which, following the debate, he had had with the Lord Chancellor. The Lord Chancellor had accepted an amendment designed to allay anxiety lest those specialists who did not join the public service might be debarred from treating their patients in hospitals privately.

Mr. C. F. **BEARE** felt that there was still ambiguity in the amendment which the Lord Chancellor had accepted. He moved, and Mr. **DICKSON WRIGHT** seconded, the following resolution:

> That this meeting of fellows and members of the Royal College of Surgeons urges the council to do its utmost to prevent the penalisation of private practice by the restriction of the medical staffs of hospitals to those who take part in the State Medical Service.

Dr. H. **GUY DAIN** said that, as far as he could see, if and when the State owned all the hospitals it would mean the end of private specialist practice. If they assented to the implementation of the Act in its present form they would immediately have to invite their private patients into newly established nursing-homes outside the Service, and even then the Act gave the Minister power to take over anything he liked, including, of course, such nursing-homes. Dr. Dain had feared for some time that consultants and specialists had not properly realised the implication of ownership of hospitals by the State.

The **PRESIDENT** said that the Lord Chancellor's assurance and the Minister's confirmation of it went some way to relieve anxiety. Members of the Negotiating Committee would, however, try to clear up the point that had been raised. They would continue to fight for the freedom of the profession.

The resolution was put to the meeting and 26 voted in its favour. Mr. **LAWRENCE ABEL** thereupon called attention to the fact that a quorum (30) was not secured and asked whether the President would consider calling a special meeting to discuss the matter. Mr. R. T. **PAYNE** supported this view and said that he was appalled at the attitude—or absence of attitude—of the hospitals.

The council has since decided that a special meeting of fellows shall be held on Nov. 29.

Buckston Browne Dinner

At the Buckston Browne dinner of fellows and members held at the college on Nov. 14, Sir Alexander Fleming, F.R.C.S., F.R.S., received the college's honorary gold medal, which has been awarded only 20 times in 144 years. Introducing the medallist, Sir **HENEAGE OGILVIE**, senior vice-president, said that Fleming's discovery of penicillin when his culture was contaminated by a mould was no more an accident than Newton's discovery of gravity when the apple dropped in his orchard.

The **PRESIDENT**, welcoming The Guests, described Mr. Bevan, who had lately paid a four hours' visit to the college, as a colleague with whom "we've got to get together and talk over these extraordinary activities of Parliament and see whether we can't make sense of them." The appeal for £250,000 for restoration and development of the college had so far, he said, produced £143,000, and wonderful opportunities lay ahead: in September the number of attendances at lectures already totalled over 9000. He was now able to announce the endowment by a New Zealand industrialist of a Commonwealth professorship of some £2000 a year enabling clinicians in the Dominions to come in contact with their colleagues in this country (see *Lancet*, Nov. 16, p. 737). This gift had been made to the College of Surgeons, but the donor wanted representatives of other bodies to help in appointing the fellows, who would generally be physicians, surgeons, or scientific workers resident in Great Britain, Australia, or New Zealand. The King had expressed his interest in the scheme, and the Prime Minister had described it as a munificent and far-sighted gesture showing "real appreciation of the needs of medicine, science, and the British Commonwealth."

Viscount **ADDISON**, F.R.C.S., Secretary of State for the Dominions, spoke of the need for exchange of high-ranking teachers between the Dominions and this country, and of the development of postgraduate study in London, which, he believed, had a finer set of teachers than any other city in the world.

Mr. **ANEURIN BEVAN**, Minister of Health, thought the New Zealand gift even more wonderful in its symbolism than in its content. In his visit to the college he had seen young men from very many countries "who had come to sit at the feet of our own teachers in London," and he felt that there was here an opportunity for something quite unique. The Government were exceedingly eager that postgraduate medical education should be developed, and would give every assistance in their power. In his period as Minister of Health "which is bound to be long and successful" he looked forward to a fertile association with the college.

Mr. W. J. **JORDAN**, High Commissioner for New Zealand, expressed his conception of Great Britain as "the centre of things," and Mr. J. A. **BEASLEY**, High Commissioner of Australia, touched on the various levels—sporting, political, scientific, medical—at which the people of the Commonwealth could learn to feel themselves part and parcel of one another, "tied together by something greater than can be written."

Mr. **THEODORE GODDARD**, as legal agent for the endowment of the new professorship, said that the donor's one object was closer contact within the Empire.

YES OR NO?

SOME PRESS REACTIONS

THE British Medical Association last week invited all registered medical practitioners to answer the question: "Do you desire the Negotiating Committee to enter into discussions with the Minister on the regulations authorised by the National Health Service Act?" The following are extracts from comments since published in the press:

British Medical Journal

What will be the position if the Negotiating Committee is instructed not to enter into discussions with the Minister on the Regulations and Orders of the National Health Service Act? The Minister, it is true, could proceed to make these Regulations and Orders with, presumably, the advice and assistance of the minority in favour of discussions. There can be no doubt, for example, that in this he would have the support of the Socialist Medical Association. He would, however, not have the indispensable support of the constituent bodies of the Negotiating Committee. The answer "No," backed by a substantial majority, would make the Act inoperable, and further legislation would be necessary to secure those principles the medical profession considers to be fundamental to its professional existence. But for the Negotiating Committee to be strongly armed in any conflict that might arise as a result of a negative answer the majority would independent effort, opportunities for settling domestic problems, for learning about social institutions, and for trying their hand at the kind of job they will eventually do. This technique has been used successfully in the resettlement of returned prisoners-of-war.

He described the case of a man on the disablement register whose difficulties had been recognised for $4^1/_2$ years, during which the Ministry of Labour had found him 46 jobs. He had taken up a great deal of the time of the Ministry, the local workers of the Provisional National Council, the disablement rehabilitation officer, and his doctors, but none of these experts in treatment, reablement, and employment had ever met together on his case. Industrial case-conferences are needed, and the Ministry of Labour might offer examination, and get a recommendation for action, from a team including the D.R.O., a social worker, a general practitioner, and a psychiatrist. Recommendations for jobs should be matched to known opportunities, and associated with a system of settlement operating not only in reablement centres but in industry.

Mr. R. E. Goll (Ministry of Labour) said that the mentally handicapped form 20 % of all types of disablement needing help; this figure is probably too low, however, for people are not ready to come forward with this type of disability. The Ministry are trying to get better ascertainment with the help of social workers. He noted that, on the advice of doctors, reablement centres are not taking psychiatric patients unless their disorders are mild; but the Ministry hopes to take over some of the civil resettlement units from the Army, as well as some of their staff to develop them. Sheltered factories, under the Disabled Persons Corporation, will take the more severely disabled, a large proportion of whom, it is hoped, will be refitted for industry. One of the difficulties at the Ministry has been due to the interpretation by lay staff of written medical reports; it is now hoped to set up a medical interviewing service, and also a diagnostic centre where patients can be observed for a time and assessed.

In the subsequent discussion a social worker said that of 4000 mentally handicapped patients in Birmingham over 60 % are employed, including many of low grade. There are plenty of routine jobs for them in the factories of the city, and an aftercare system has been active since 1901; but even so, much work is needed to get these good results. Subnormal people are easily put off, and every grievance has to be investigated at once.

Community Care

At the afternoon session Mr. P. Barter (Board of Control) took the chair, and Prof. Aubrey Lewis opened a discussion on community care in relation to the extended powers of health authorities under the National Health Service. He regretted that the authority responsible for community care will usually be different from that responsible for hospitals and clinics, but hoped that the same doctors, psychologists, and mental-health workers as are employed by the regional authorities may also be able in some cases to work for the local authority on a part-time basis, so ensuring continuity of personal care for the patient. He referred to Dr. C. P. Blacker's report, *Neurosis and the Mental Health Services*, as the vade-mecum of those who execute, and the bible of those who plan, the mental-health services. The National Health Service Act provides the means whereby his recommendations could be made actual, provided enough people of the right kind can be found to work in it. Children will demand much attention, but the elderly will soon make up the bulk of people needing psychiatric care, and their demands may drain time and effort which might otherwise be spent on younger people—a dangerous situation. Psychiatric outpatient departments must be more numerous, flexible, and generously staffed, and must concern themselves more with following up, and with the use of social resources. The psychiatrist, the general practitioner, the psychologist, the psychiatric social worker, the nurse, the health visitor, and the personal manager or welfare officer all have their place in the care of the mentally ill.

Professor Lewis believes that boarding out of patients might be used much more freely in the care of mentally ill patients: it is practised successfully in France,
Germany, Scandinavia, Switzerland, and the Un
States. He quoted the finding of Miss Crutcher
success depends on the amount of time given to the
of these patients by psychiatric social workers. In
long run it offers an economy in the cost of mental
vices, and—more important—means for many incur
patients an increase in happiness.

During the last twelve months some 5500 patients h
been referred by civilian agencies to the aftercare ser
offered by the Provisional National Council—a strik
illustration of the need for a national mental-he
service. But there must be economical use of
present resources in trained people: the social work
of each region should be attached to the mental-he
services of that region, and the activities of the
visional National Council should be a part of the hea
service rather than a separate social service or a
of the social services provided by the local author
Four factors set limits to what we may hope to achie
(1) the number of trained people available; (2) the st
of public opinion and knowledge about mental heal
(3) the state of expert opinion and knowledge;
(4) the intimate dependence of mental health upon
social fabric. In view of the general shortage of m
power, Professor Lewis thinks economical use of
people already in the field, and better training of th
now entering it, will provide the necessary staff bet
than competitive efforts to attract more young men
women into these careers.

Dr. W. S. Maclay (Board of Control) suggested t
the various authorities in a region should collabor
and use each other's officers. He hoped the officers
take over the duties of the relieving officers will m
use of specialists in the home whenever their help
desirable. He mentioned that transfer to hospital
be frightening for the patient: care on the journey
not always satisfactory. The patient should be atten
by trained nurses from the hospital to which he is go
In order to prevent confusion in the use of psychiat
social workers, he suggested that the patient should
under the care of the hospital social worker as long
he is attending outpatients, and should be transfer
to the local-authority social worker only when he
longer needs the help of the hospital.

Dr. Thomas Beaton (St. James Hospital, Portsmou
said that in his city the mental-health service covers
whole field, and he was nervous lest the new Act sho
separate the community service from the hosp
service. Dr. Doris Odlum thought the local authori
have a special opportunity in the field of preventi
and since early diagnosis means better results she wo
like local authorities to set up adequate outpati
clinics, staffed by psychiatrists and social worke
Mr. Bainbridge thought ascertainment is bet
achieved through the local health authority than throu
hospitals. Dr. E. Cunningham Dax (Netherne H
pital) had some concrete plans for the elderly.
had analysed the histories of 250 patients over six
and had found that 80 % either die or are discharg
within six months of admission to hospital. He suggest
that hospitals offering six months' care might be provid
for patients over sixty; while something more like
home-from-home might be provided for the 20 % w
still need care at the end of that time.

THE MINISTER'S VIEW

Mr. Aneurin Bevan, Minister of Health, said that t
duty of the Ministry has been to put at the disposal
mental-health workers the best possible administrati
apparatus, and to leave them to use it. Some feared th
the Minister would impose his "almost illimitat
ignorance" on the technical workers in their speci
fields, but it was not his business to dictate how th
should use their special knowledge—only to put the be
kind of facilities at their disposal. The new schem
should extend, not reduce, voluntary activities.
reminded the meeting that ours will be the first nati
to remove financial anxiety from between doctor a
patient—and a financial anxiety neurosis is as bad
any other. The different organisations under the heal
scheme will be coördinated by the fact that the M.O.
the general practitioner, and the specialist will all
common users of the same facilities: and access
those facilities cannot be denied to any citizen. A variet

In England Now

A Running Commentary by Peripatetic Correspondents

QUITE a short residence in South Africa immunises me against surprise at anything the medical profession may say or do. Consequently the announcement of he South African Medical Council, as reported in the morning paper today, that articles in the medical press must be unsigned hardly interfered at all with the downward progress of one's breakfast egg. One merely wondered whether it was going far enough—the S.A.M.C., I mean, not the egg. Should we not walk around masked, be better to preserve our anonymity? No, perhaps not, for I have never noticed any eclipse of a surgeon's personality by his cap and mask—rather the contrary.

With my experience of unit censorship I'm just the man for the job of rendering anonymous the textbooks in the library. And what fun I should have with that book on surgery by X and Y. Mr. Y, who called me rude names in my Conjoint surgery—and I failed—will be radically excised with the scissors. Mr. X, whom I met later in the M.B. viva, was charming throughout and gave me a pass mark. His name shall receive merely a token stroke with the blue pencil.

* * *

Last night the medical superintendent of one of the Chinese hospitals came to my rooms and said: "This is the day the managers hold their quarterly meeting. There's a feast for the staff afterwards. Why not come along?" I gladly went. "Don't," he advised, as we neared the place, "eat much of the first few courses. If you do, you'll never get through the meal. Well, here we are. This is the nurses' dining-room."

Some fifty girls and a dozen men rose to their feet at our entrance and looked towards me in respectful silence. I began to feel a little like a god. My host introduced me in Chinese. I don't know what he said, but everyone suddenly burst out laughing and bowed me in with enormous grins. I stopped feeling like a god and sat down on a couch next to a rather pretty nurse. I opened my mouth to frame a halting Cantonese "Hallo," but a waitress smartly plugged the gap with a cigarette. Another lit it, a third handed me a glass, a fourth half filled it with whisky, and a fifth added a grudging hint of water. "There!" said the rather pretty nurse. "Now you're all right." Thenceforth we discussed each other happily in English.

Ninety minutes later I stood up just the least bit deliberately in response to a general move towards the food. By this time the rather pretty nurse had become quite beautiful; so had the other forty-nine; and the men appeared as bold Apollos set in a field of lovely Daphnes. The meal was served at small round tables, and the Daphnes, as Daphnes always will. tended to bunch into strong, protective groups. Five minutes' good clean fun was had by all while the bold Apollos sorted the Daphnes out. I kept close tag on the rather pretty nurse, for she, dear girl, had promised to help me wield the chopsticks. How would the matron of my own grave hospital have borne the sight of her carefully cultured chicks dodging in squeaking ecstasy round the furniture, hotly pursued by the board of management?

And goodness, how those girls did eat! Shrimps and oysters, bamboo shoots and pineapples, all mixed up into one glorious dish; fried rice and nuts and mushrooms; shark's fin soup; boiled chicken; plovers' eggs; roast duck (the duck was cooked to a limp rag—we only used the gravy); boiled frogs (tasting like rabbit); fried fish; fat pork (soft as a jelly-fish); fried prawns; pêche Melba; and green tea. As each enormous dish was placed on the table out shot a baby forest of chopsticks, and in a matter of seconds the platter was empty, every scrap transferred to the bowls from which we ate each course in turn. I had the special protection of a waitress who did the preliminary forage work for me. Had my Daphne done this she would never have salvaged a morsel for herself. Not till the centre dish was empty could she afford to rest and guide my awkward sticks.

Meanwhile the managers were hard at work. After the first keen appetite was dulled they started on the healths. These were intensely personal affairs. A man would charge his glass, pin-point his victim, run up to him, and loudly shout the toast. Then it was "bottoms up" without the option. I, as the only stranger there, came in for more than my fair share of bottoms up. I strove to uphold British honour and prestige by keeping a glass of water tinged with soya sauce at hand, ready for instant draining.

At length the feast, starting in busy silence, rising to noisy merriment, sank to a stage of sleepy satisfaction. Two or three managers arose and bade farewell. They had a business dinner to attend elsewhere. One of the housemen went to the piano. "Now," thought I, "some Chinese music; just to round things off." First he played "Onward Christian Soldiers," then "Abide with Me." All sang. A few more hymns, until, in deference to popular demand, this Oriental evening closed to the strange sound of over fifty Eastern voices chanting with sentimental joy: "My Little Grey Home in the West."

* * *

The Hetherington report on domestics, the Rushcliffe report on nurses and midwives, the Spens report on medical practitioners, the Askwith report on public-health medical officers, and the National Joint Council agreements on various staffs are playing pranks in local-government circles. Maids often get more than assistant nurses; the intake of student nurses is falling because girls can make more, and think they have a better time, working in shop or office where their leisure is not tampered with; and various medical auxiliaries regard each other with some asperity because there is a £10 difference between their basic salaries.

The poor old Askwith horse, however, has already more jockeys than it was ever meant to carry. Designed for medical officers in the health service, the scales are already being adopted by other local-authority officers as levers to salary promotion. Why, it is argued, should the medical officer of health have more than the gas engineer or the treasurer—so up goes the salary of these officials. Why, says the town clerk, should the deputy town clerk have less than an assistant medical officer of health—so up goes the deputy town clerk's salary. It all seems very illogical, but there it is.

So now, in these days of the closed shop, and feeling somewhat insecure as a medical officer of health, I am thinking of joining the County Clerks' Trade Union, or, better still, that of the Chief Electrical Engineers, just to see if I too can bestride an alien nag and ride home to win £3000 a year.

* * *

It is one A.M. again, and I am facing what always seems to me one of the worst half-hours in the G.P.'s life. Twenty minutes ago, bathed, relaxed, and rejoicing in my newly donned winter woollies, I was at peace. Nineteen minutes ago I was listening to an anxious voice saying, "The wife's hot and cold all over, doctor. Can you come at once? I think it is serious." Long experience has taught me that when such a summons comes to obey is the lesser of two evils. If I don't go I spend the rest of the night either reproaching myself for my unkindness or visualising the patient dying of some obscure complaint which I alone could cure. If I go my conscience lets me alone. But having gone, why is it so difficult to make an unbiased diagnosis at midnight? The patient is dyspnœic. She says she is in agony and can't speak. The pulse is rapid but of good volume. It looks like the old story of "wind with wind up," but I can't be sure. However, I prescribe bicarbonate, sugar, and water and retire downstairs to drink a cup of tea with the husband, who miraculously seems to have forgotten his worries and starts to tell me about his new job on the railway. To a layman and to a better doctor the thing would be finished and forgotten. But it is not like that with me. Back in bed the darkened room seems to clear the mind and call up forgotten diagnoses. I recall a case where, having reassured the relations and told them there was no cause for worry, I was accosted next morning by those selfsame relations. "Can we have the certificate, doctor? We want to get the funeral over before the weekend." In my mind's eye I see our coroner no longer his usual kindly self but full of scathing comments on the folly of spot diagnoses at midnight.

But time marches on. It is now one thirty and the husband has not phoned again. My medicine must have worked. The patient is asleep and will not die tonight and perhaps now the half-hour is over I too may be permitted a little rest.

have to be substantial and firm in its purpose. It is, of course, obvious that if the medical profession was so set against the Act that it felt unable to work under it such a decision would in no sense be illegal or in the nature of a strike. Doctors do not strike. They will always continue to serve the sick public. An Act is not necessary to make them do this. It would simply mean that they would not serve the sick public within the framework desired by the Government of this country. The Minister fully recognises the right of the individual medical man not to enter the Service, so a decision not to enter into it would be strictly legal and honourable.

DR. GUY DAIN (*chairman of council, B.M.A.*)

We have just learned that a strong and concerted action will force the Minister to do something which he was entirely unwilling to do. The threat—it was no more than the whisper of a threat—that insurance practitioners would resign if he would not agree to implement the Spens Report brought him to heel at once. Here we have an opportunity of saying that we will not take any part in a service that does not concede our principles. Why should we not get our principles accepted as well as the conditions of service ? The conditions will have to be argued afterwards anyhow. Why not insist on our principles being established, by an amending Act or whatever it may be, before we agree for a moment to talk on terms and conditions ? We should be no worse off ; indeed we should be infinitely stronger in talking about terms and conditions if we had first by our own efforts secured the acceptance of our principles. . . .

We want to put into the Act the right of every doctor to come in, and the right of appeal to the courts from the Minister's decision to take us out of the service ; we want removed from the Act the State ownership of hospitals, the embargo on the buying and selling of practices, all direction of general practitioners, and the salary element in general practitioners' remuneration ; we want altered the procedure of election on to the councils and committees so that we may nominate our own representatives instead of the Minister choosing them all, and in that way we may curb dictatorship in the service. (*Brit. med. J.* Nov. 16, p. 747.)

MR. HENRY SOUTTAR (*late president, B.M.A.*)

To me it is intensely disappointing that the association should now refuse to assist in the completion of a project to which they themselves gave birth, the great conception of a universal medical service for the whole nation, and it is of grave import that they should resist the implementation of what is now the law of the country. If they persist in their refusal it only means that they will have no share in the control of a great enterprise, for I am certain that the medical profession will never refuse to serve the nation. The points at issue are of secondary importance, upon many of them there is no general agreement, and they furnish no possible justification for the statement that the liberty of medicine is at stake. I trust that doctors throughout the country will refuse to be led into an untenable situation which could only bring discredit upon us all. (*Times*, Nov. 19.)

Medical Press

What would be the effect of the decision " no " ? This, of course, is primarily a matter for a Constitutional lawyer, and it is a field into which we would not presume to enter. But in the mind of the ordinary man or woman it would surely be tantamount to a decision not to coöperate with the Minister in the working of the new Bill, which again would be tantamount to a refusal to accept the decision of Parliament. In our view, for what it is worth, to vote against negotiations would be a very perilous course for the profession to take. . . .

Technically, perhaps, as the *British Medical Journal* emphasised in its Editorial of November 16, it would not be a strike. " Doctors do not strike. They will always continue to serve the sick public. An Act is not necessary to make them do this. It would simply mean that they would not serve the sick public within the framework desired by the Government of this country."

But if not, as we have said, technically a strike, such action would so very closely approximate to a strike that it might be hard to detect *the difference*, and we would certainly not expect the general public to make such a delicate differential diagnosis. It would almost certainly be construed as a defiance of Parliament, and it might well initiate a struggle in which no support from *any* responsible political quarter could be expected. (Nov. 20.)

The Times

With the ballot form sent to each doctor are enclosed
comments on the Act of the joint committee of the me
organizations which has been *negotiating* with the Gov
ment. This disappointing and somewhat partial docu
has nothing to say in praise of an epoch-making me
beyond a grudging acknowledgment that " the constru
proposals of the profession are reflected in certain sec
of the Act." It contains no appreciation of the
substantial concessions to the interests of doctors w

births), including 26 in London.

rsing and hold precisely the same academic rank as their w deans in other faculties. At Vanderbilt the school of ing is one of the seven independent schools of the univer- with its dean at its head. It has its own financial resources makes its own annual budget. Since 1935 all costs and onsibilities relating to nursing education and nursing ice have been separate. A director of nursing services urse) is in charge of the hospital nursing service, and each d unit has a head nurse in charge. The superintendent of hospital (a medical man) is responsible to the dean of medical faculty, and the director of nursing services is onsible to him.

he school of nursing employs a full-time staff of clinical ructors (nurses), who are members of the faculty, not of hospital staff, and also utilises the services of the professors lecturers of the faculties of medicine and science (for ch it pays). The dean estimates the exact number of rs of clinical experience in all nursing and public-health ds that she requires for her students and requisitions se from the services concerned. The director of nursing vices, on her side, knows how much clinical assistance can expect from the students, and plans staffing cordingly.

The hospital provides maintenance (room, board, and ndry) for the students at a hall of residence in return for eir clinical work in the wards, and to cover the "freshman" riod of ten months while students do not enter the wards school pays the hospital a "blanket" sum for freshmen's aintenance. Students of nursing mix with students in other ulties (*Amer. J. Nursing*, 1946, 46, 550).

Mrs. Bennett came back greatly impressed by and vious of what she had seen but convinced that Britain ust work out its nursing problems on its own lines. either do I suggest that we want uncritically to import merican and Canadian methods. But we do contend at unless and until the "profession" of nursing to hich so many people pay lip service has its own faculty ith an intellectual discipline as satisfying and as xacting as that of other faculties it is not in truth a rofession.

Moreover, I believe that if a university school of nursing ould be started on experimental lines it would imme- ately attract students of the quality required, who ould have the courage and the imagination and initiative o realise that their concern would be to break away from tradition if necessary, and not to rest until the needs of all patients—acute and chronic, the young and the old—for nursing service and for health education were fully met. Believing this I cannot think that a "medical dean of nursing" would be an advantage to us. To quote Emily Davies in the pioneering days of the omen's colleges: "We are really obliged to Convocation or their kind intentions in offering us a serpent when e asked for a fish, though we cannot pretend to believe that serpents are better for us."

London, W.2. G. B. CARTER.

MALIGNANT GRANULOMA OF NOSE

SIR,—Mr. Hargrove and his colleagues (Oct. 26, p. 596) state that the cause of this condition is unknown. I think it may be linked up with cutaneous gangrene.[1] There has also been an interesting paper on bony changes associated with tropical ulcer.[2]

It is significant, I think, that Mr. Hargrove's case responded to penicillin, since this has been found effective by others.[3,4] Even more significant is the account from the Mayo Clinic of spreading osteomyelitis of the cranial bone.[5] The work was based on the report by Williams and Heilman[6] that a micro-aerophilic short-chained streptococcus is responsible for the malignant type of osteomyelitis; the Mayo Clinic workers found this organism sensitive to penicillin. Meleney recommended a special active preparation of zinc peroxide, while I have found powdered potassium permanganate effective.[1]

St. Margaret's Hospital, Epping, Essex. FRANK MARSH.

TUBERCLE BACILLI IN CEREBROSPINAL FLUID

SIR,—In your report (Oct. 12, p. 528) of the September meeting of the Tuberculosis Association, Dr. Honor Smith is reported as saying, "unfortunately, tubercle bacilli could seldom be found in the cerebrospinal fluid" (in cases of tuberculous meningitis). I must dissent from this view. Examining fluids in our own laboratory, we have not failed, for several years past, to demonstrate the tubercle bacillus in every case of tuberculous meningitis coming under our care. Nearly always the first (and only) specimen drawn by lumbar puncture yields the organism; rarely, examination of a subsequent specimen is required. I would indeed go so far as to say that the bacillus may *almost invariably* be found before death in the cerebrospinal fluid from a case of tuberculous meningitis, provided only that the searcher is both adept and persevering. NIGEL W. ROBERTS.

Hull City Isolation Hospital, Cottingham.

EXCISION OF THE HEAD OF THE PANCREAS

SIR,—In your admirable editorial on excision of the head of the pancreas (*Lancet*, Sept. 14, p. 380) the present position is concisely set out.

Whipple has clearly shown the advantages of the one-stage operation and has enumerated the objections to using the gall-bladder for the relief of biliary obstruction. The main steps in the operation, as outlined in recent excellent papers by Whipple and Pannett, are: (1) relief of biliary obstruction; (2) diversion of gastric emptying from the duodenum to the jejunum; and (3) division and removal of duodenum and head of pancreas, with anastomosis of residual pancreas to jejunum. These steps should be taken in this order. In discussing the first step you refer to the use of the gall-bladder for this purpose as "an unavoidable expedient in the two-stage operation." May I be permitted to disagree, and to suggest that it is possible to join the common bile-duct to the jejunum without increasing the difficulty of the subsequent steps? Moreover, while it would appear foolish always to adhere rigidly to a one-stage operation, yet the patient might well be able to stand more than mere relief of the obstructive jaundice at the first stage. The deciding factor must always be the patient's general condition and how well he will stand up to the anæsthetic and operation. This cannot be accurately forecast in every case, so one should be guided in deciding how much to do by the progress of the operation. It may often be possible to carry out the first two steps (described above) at the first operation, thus helping to equalise the two stages.

If a long jejunal loop is turned up through the transverse mesocolon, the divided common bile-duct can first of all be anastomosed to it. The distal end of the bile-duct, divided low down behind the duodenum, is securely closed with interrupted silk sutures. Then, if the patient is faring well, the stomach is divided through the pyloric antrum, the distal end closed with silk sutures, and the proximal end united to the jejunal loop well beyond the biliary anastomosis. If the patient is still doing well, the third and biggest step may be attempted. This needs careful consideration and fine judgment since, once begun, it must be completed.

These remarks are based on recent experience in operating on a man, aged 70, with very severe obstructive jaundice due to carcinoma of the head of the pancreas proper. After careful preoperative investigation and preparation, his abdomen was explored with the intention of performing as much as possible at the first stage, should two stages be necessary. The procedure described above was followed, but it was thought wise to stop at the end of the second step. This left room for anastomosis of the residual pancreas to the jejunal loop between the biliary and gastric junctions at the next stage. Unfortunately there was a delay of over two months before this next stage could be attempted, owing to threatened strangulation of a large right inguinal hernia, and an operation for a strangulated left femoral hernia, followed by uræmia due to retention of urine. Despite this delay, no undue difficulty arose from the steps of the first operation; but considerable difficulty was caused by adhesions, fat, and friable veins, especially

Letters to the Editor

THE TEACHER'S INCOME

SIR,—Lord Beveridge has put on record [1] his opinion that the medical profession should be paid more than the university teaching profession because the medical profession has to work harder at less regular hours and must deal with a proportion of unattractive patients.

Both of us who sign this letter have had experience of the university teaching profession and we feel that Lord Beveridge's statement calls for some discussion. How much more would Lord Beveridge pay the medical profession than the university teaching profession? A reasonable case can indeed be presented in favour of compensating for disturbed nights and disagreeable patients—although, among medical university teachers, pathologists and bacteriologists might claim that their work was often physically disagreeable and sometimes dangerous. But, on the whole, university medical teachers would not seriously object if their clinical colleagues were paid something extra for disturbed nights.

But in calculating the difference, account must be taken of demands on the "leisure" hours of university teachers that are made by carefully studied, often complicated, experiments and extensive scientific reading—both essential activities for a teacher who means to serve his students faithfully and make any progress in his profession. What must be avoided is perpetuation of the economic gulf which now divides university teachers from their clinical colleagues—with whom, in our teaching hospitals, they work daily on equal terms, sharing responsibility and contributing at least as much to the care of the sick.

In the past, university teachers have philosophically accepted that professors alone could hope to reach an income which was only slightly less than that of a moderately successful general practitioner and perhaps about one-fifth of that earned by a successful consultant in the same hospital. This unfair distinction was the outcome of blind economic force, and it was not their habit to be distracted by the chaotic values of the market-place.

But we stand now in face of a planned medical service, and the university teachers may feel less philosophic if Lord Beveridge and the planners decide to perpetuate the financial penalty upon academic workers. The market-place may please itself, but it will not do for the State to set a comparatively low value on the services of those who are to train its doctors, serve its great hospitals, and lead its medical thinking and research. Lord Beveridge may be right in asking for some difference in favour of clinicians, but the difference must not be of the order that now divides lecturers and professors from practitioners and consultants, or it will have a serious bearing on the quality of graduate who may be attracted to teaching and research when practice (in and out of hospital) becomes decommercialised and therefore more likely to attract men of academic outlook.

Aberdeen. JAMES W. HOWIE.
Leeds. GEORGIANA M. BONSER.

CORONARY DISEASE

SIR,—In your number of Nov. 9 Professor Ryle suggests that the incidence of coronary disease is some $3^{1}/_{2}$ times greater amongst professional men than amongst so-called working-class men. Observations made in the Post Office a few years ago are fully in accordance with this. But when, in discussing its ætiology, he states that "the amount of mental work and emotional stimulation now possible in the course of a single day is something far in excess of anything experienced by our ancestors," and that this may be an ætiological explanation, I would venture to express a doubt.

Here he appears to associate himself, in respect of coronary disease, with many others who assert that there is an increase in neurosis and nervous instability and that this is due to the increased "pace and pressure" of modern existence. But in respect of both these assertions it is surely not possible to make any accurate comparisons. The data do not exist. Yet, as regards alleged increase of nervous disorders, any even cas reading of seventeenth- and eighteenth-century nov diaries, and correspondence suggests that vapours, swo ings, and a liability to dissolve into tears were as comn then amongst young women and men—and indeed v possibly commoner. And amongst rural and other po lations that did not keep diaries or write letters or written about, was there not—on existing evidence— least as much anxiety and obsessional and other neuro due to beliefs in witchcraft, the evil eye, and a flam hell after death—to say nothing of the fear of physi violence, hunger, and a savage penal code?

Did not the Elizabethan day, whether in court country, navy or counting-house, contain at least many stimuli to mental activity and emotion as toda Is life in London now, for all its "pace and pressur fuller of malign influences upon body and mind th the London of Hogarth's Gin Lane or the London Pepys? If motor-buses travel at 30 miles an hour our suburban lanes, it is at least through lanes that free from highwaymen. If the wireless fills the coun cottage all the evening, it is at least to that extent oust ignorant gossip or the solitary brooding begotten of lo superstition. And has this alleged increase in "p and pressure" of modern life imposed upon the hum nervous system anything comparable with the burden th anæsthesia, for example, has lifted?

London. H. H. BASHFORD.

NURSING

SIR,—Discussion of the nursing problem is apt obscure the fact that at least three aspects requ consideration: (1) the needs of the patient; (2) natio allocation of man-power; (3) the nature of the wo to be done by nurses and their suitability and traini to do it.

In my judgment, (1) should be thrashed out in each of t regions of the National Health Service, by mixed committe representing everyone concerned—patients and the heal team (i.e., doctors, nurses, domestic workers, dietitia almoners, physiotherapists, occupational therapists, tec nicians). A directive and terms of reference might profitab come from the Ministry of Health to keep discussion with bounds. There might result surprising repercussions staffing. The second aspect would require man-power budge from each profession and trade making demands on t national man-power pool. Claims would have to be reconcil and dovetailed by the Ministry of Labour and Natio Service and should lead in every field to much-needed resear on optimum use of man-power, methods of education, a adjuvants to labour. The third aspect will obviously modified by the results of (1) and (2) but it seems certa that most recruits to the "nursing services," as defined, w eventually consist of carefully selected women (and so men) of the right temperament and of moderate education attainments, with a percentage of able women, and perha men, who must become highly qualified to teach, organi and direct the service as a whole.

For many years hospitals have aimed at recruiti near-matriculated and matriculated girls as probationer A high proportion of these entrants leave the nursi services, and the best of those who remain feel frustrate because their status is permanently inferior to the oth matriculated students who become doctors, teacher almoners, secretaries, &c. The reason is partly that the training and preparation actually are inferior in content, you point out, to other professional disciplines, and partl that the medical profession, except a minority, hav never been prepared to accept nurses as colleagues.

The stimulus to these remarks is the suggestion i your issue of Oct. 26 of a "medical dean of nursing who should "feel himself or herself to *be as muc responsible for the proper training of the nurses as the dea of the medical school is for his students.*"

It has been my good fortune lately to meet severa deans of nursing schools—all nurses—in the flesh. have also had much information from Mrs. B. A. Bennett chief nursing officer of the Ministry of Labour an National Service, recently back from an extensive tou in the United States of America and Canada.

At Vanderbilt, Yale, Toronto, and several other universit centres there are deans of nursing schools who are professor

---

[1] *Hansard*, Oct. 9, par. 94; see *Lancet*, Oct. 26, p. 596.

Dr. Frank found that after a certain number of convulsions patients reached a plateau level of over-politeness, or in English they were well cowed; and I suppose it could be argued that therapeutic terrorism and scientific bullying are justified by their results: but to call the process an altering of "faulty electrical patterns in the brain" is silly. If these words have some occult meaning which space did not allow him to impart, then I shall apologise to Dr. Milligan. Meanwhile, perhaps you will allow me to copy him in recording my belief that the page in the history of our mental hospitals which is being written now will present a pattern of considerable avidity.

Beckley, Rye. C. G. LEAROYD.

THE REGIONAL BOARDS

SIR,—The letter from Sir Leonard Parsons last week is extremely opportune. It is based on great experience and is entirely helpful.

Since the population of regions may run to 3 million, boards will be quite unable to manage the day-to-day affairs of district and smaller hospitals, and, in view of their extensive commitments, it is pretty certain they will avail themselves of the help of the great body of experienced people now engaged in settling the current affairs of those hospitals.

It seems to me the boards must be mainly "administrative"; but does that preclude their preoccupation "with broad lines of policy"? If rightly chosen it may well be an enlightened and imaginative administration. If we judge by the success of the great boards and "authorities" of recent creation, controlling activities in other spheres, it looks as though democracy was beginning to appreciate the importance of leaving supreme control to those with a lifetime's experience of the actual working of an undertaking and giving them a free hand to choose their own administrators. As we well know, only those who *do* the work understand its complications and requirements. It is for them to tell the administrators *what* they should provide, and explain how *not* to do it. The administrators will find the right way to do it. Experience of hospital boards shows that proposals from a medical committee for improvement of service to the public or for the betterment of patients, based on informed opinion and lucidly presented, are very rarely rejected by a lay committee. If not at once accepted on some ground of general policy or finance, even then they are merely postponed until conditions can be created in which they may be implemented.

It is then of the greatest importance that action should be initiated by professional counsel. As Sir Leonard says, it will be for the administration, and its executive officers, to find the best way of attaining the end desired.

Medical advisory committees should be constituted, if not before, at least simultaneously with the boards. In several regions temporary bodies serving just that purpose already exist. They have done a great deal of admirable work, much of which can be studied in published reports but should be more widely known.

In addition, many of the specialist associations have devoted a lot of time and thought to the preparation of plans for regional services, and fortunately some of the plans are based on experience derived from successful working of such schemes under the Emergency Medical Service. That service had far less power and fewer resources than will be at the disposal of the boards.

When boards first sit all this information will be available for their guidance, but much more on the same lines could be done to simplify their task. There are, for example, places where forward-looking people have considered in detail what will be the duties of a local management committee in regard to a group of hospitals. Is it not highly probable that a board will thankfully accept, at least in broad outline, plans so prepared? Ought not the same sort of activity to be initiated everywhere? Will it not be the fault of the profession—medical, dental, nursing, social service—if a newly constituted board has to begin by gathering with great expenditure of time and trouble information and advice that ought to have been prepared by us in advance?

With regard to the choice of officials it is to be hoped that no one pattern will be adopted for all regions. No-one yet knows what is the best plan. Nothing but good can come from diversity of method in the early stages. Who knows for certain whether the chief administrative officer should be a layman or a medical man? Why not try both plans if the right individuals can be found?

London, W.1. E. ROCK CARLING.

Medicine and the Law

No Fee, No Damages

A RECENT decision in the Dublin courts may have surprised those who study the liabilities of hospitals. Daniel Walsh went to the Cork District Hospital to be operated upon for varicose veins. He complained that some of the anæsthetic was somehow allowed to enter his eye. The judge found that the patient went into the hospital with two good eyes in September and was discharged in January with the sight of the left eye gone. Walsh sued the South Cork board of assistance. The board denied negligence and further pleaded that they owed him no duty. The judge held that, as Walsh was a non-paying patient, he was not entitled to recover from the board, even if there had been negligence.

One would like to see the full statement of the grounds of the decision. The courts of Eire are presumably still administering the common law. It is difficult to find any analogy in English decisions. In an old case, where the facts had nothing to do with medical treatment (Shiells *v.* Blackburne, 1789), a judge expressed the following view: "If a man applies to a surgeon to attend him in a disorder for a reward, and the surgeon treats him improperly, that is gross negligence and the surgeon is liable to an action. The surgeon would also be liable for such negligence if he undertook gratis to attend such person, because his situation implies skill in surgery. But if the patient applies to a man of a different employment or occupation for his gratuitous assistance, who either does not exert all his skill or administers improper remedies to the best of his ability, such person is not liable." This case is still cited in modern textbooks.

The liability of a public body for mistakes made by the employees or professional men whom it chooses is, of course, a more complicated matter than the liability of doctor to patient. These problems perhaps will diminish when State insurance covers all accidents and when the State health service includes nearly all medical practitioners.

The Foundling's Birth Certificate

A letter in the *Times* on Oct. 29 and subsequent correspondence have again drawn attention to the unhappy consequences of the disclosure in birth certificates that the person to whom the certificate relates is illegitimate or a foundling. It has been suggested in several quarters that the certificate should omit details which may thus cause pain and prejudice. The proposal would require legislation. The Registrar-General has powers of prescribing forms, but he is obliged by statute at present to see that certain facts are furnished on a birth certificate. Only an Act of Parliament can authorise him to cause something less to be furnished.

There may be no chance, in the existing conditions of streamlined law-making, for the necessary Bill to be introduced. The suggested reform of the foundling's certificate is just the kind of matter which a private Member of Parliament might have taken up. For the past eight years, however, no private Member's Bill has been permitted. The attention recently aroused might usefully lead to the general overhaul of our registration laws. They date from 1836. The world has moved since then.

in isolating the mesenteric and splenic vessels. In spite of this the operation was completed satisfactorily, though unfortunately the patient died on the second day from heart-failure.

ALAN SHORTER.

Mount Vernon Hospital, Northwood, Middlesex.

THE PLEBISCITE

SIR,—Now that the National Health Service Bill has become an Act, it is only at grave risk to their whole future that members of the medical profession can postpone any longer becoming acquainted with the essential features of the measure and making up their minds with a view to appropriate action. This might not have been an easy matter in any circumstances, but it has been made unnecessarily difficult by the confusion of the issue due to the early agreement of the leading political parties and the (probably now repentant) executive of the B.M.A., without a mandate from the representative body, to adopt the principle of a "comprehensive" and centrally controlled service for the nation. By this arrangement before the "fight" began, all they wanted was handed on a plate to the plotters, and all that followed was merely a wordy conflict waged over the whole field of relatively unimportant details. The final act of folly would be to negotiate a settlement on the basis of regulations which the Minister of Health and his successors could alter at will to suit their convenience or at the behest of party bosses behind the scenes.

Above the din of propaganda it is difficult to hear the still small voice of truth; but one thing which must not be missed is the fact that what Parliament has passed is practically an enabling Act giving the Minister of Health dictator powers over those who join the new service. An examination of the Act will reveal that it is an instrument admirably designed for the enforcement of a hidden policy. In this connexion it should be observed that it is a centrally controlled organisation with comprehensive powers over great masses of persons and is *therefore potentially an instrument of aggression, a secret* weapon, a mechanism of dictatorship, capable of being used for the regimentation of the medical profession and of the public whom it serves, prepared in advance against the day when a minority political group, having seized power, is in need of a means to impose its policy upon the people of this country.

In face of all this, what should our policy be—appeasement? No. "He is a foolish man who thinks he can appease a wolf."

The plebiscite—this is not *the* crucial decision: this is OPPORTUNITY writ large. To answer "No" can do no individual doctor any harm, now or in the future. On the contrary, it may save him from the crucial dilemma, at a later stage, of having to choose between enslavement and the risk of starvation for himself and his dependants. It may save the profession and the nation from a great deal more besides.

Bexley, Kent. E. U. MACWILLIAM.

SIR,—May I, through your columns, appeal on the widest grounds to all members of our profession to answer "Yes" to the "plebiscite" sent us by the secretary of the British Medical Association? The Bill has become the Act. The nation has decided that it will have a National Health Service, and in this Act has laid down the general principles under which this should be organised. It is now the time for the details to be filled in by cross-table discussions between representatives of those who serve and of those whom we are to serve. This is not a time in which to hesitate in the service of the State, or for those who have been appointed representatives of all the leading medical bodies in the country to leave, with their work half done, the plough to which they have been called to put their hands. Let us by our votes tell them we think that they should go on.

London, S.E.1. T. B. LAYTON.

SIR,—I am enough of a Socialist to believe that *all* diagnosis and treatment should be available to everyone. Thus far I am sure that most of the profession agree whole-heartedly with Mr. Bevan. But before giving our coöperation in running a new health service we must be sure how large a proportion of those involved, the public and the doctors, will suffer, and what are the compensating gains.

It is clear that better financial backing is neede
the hospitals, and this can surely best be provided b
State. A measure of control of spending is c
necessary; I am not qualified to discuss the pro
method of exercising this control. With regard t
general practitioners, it appears to me that the
reason for the undoubtedly better treatment of the
wealthy patient is that his doctor can afford to
more time with him. The rich man's doctor has
patients and they pay more. The doctor in a wor
man's practice must have more patients since he is
less for each. Improvement can only be obtaine
restricting the working-man's doctor to fewer pat
(and clearly more doctors will therefore be requ
and by paying him more. Mr. Bevan is already pre
the medical schools to take more medical stud
He has, however, refused to make the increases in
ment to the panel doctor suggested by the Spens
mittee. The alternatives to which the panel practiti
will eventually be driven, then, if a capitation basi
payment survives, are either to give up some o
patients and reduce his standard of living (this is
trade-unions call "dilution") or to attempt to cont
his unsatisfactory existence as at present, not ha
the time to do his work as he would wish. His dec
will be helped perhaps by the "indirect directi
of other doctors into his practice; the unempl
doctor, perhaps newly qualified, will probably have

Obituary

LOUIS EDWARD BARNETT

KT., C.M.G., M.B. EDIN., F.R.C.S.

Sir Louis Barnett, a founder and past-president of the yal Australasian College of Surgeons and emeritus fessor of surgery in the University of Otago, died in nedin on Oct. 28 at the age of 81.

The son of the late Alfred Barnett, of Wellington, he an his medical education in New Zealand and was ong the earliest students at the Otago medical school 1883. He graduated M.B. at the University of Edinburgh with first class honours five years later, and after holding a house-appointment at the Middlesex Hospital, London, he took the F.R.C.S. in 1890. The following year he returned to New Zealand to become surgeon to the Dunedin Hospital and acting lecturer in surgery at the University of Otago. His appointment as lecturer was confirmed in 1896—at a yearly salary of £125—and in 1909 he was appointed to the chair which he occupied till 1924. After his retirement he endowed the chair in memory of his son Ralph, who had n killed in the first world war. From 1914 to 1918 Louis himself served with the R.A.M.C. and N.Z.M.C. consulting surgeon with the rank of lieut.-colonel, he was appointed C.M.G. in 1918.

arnett had made a special study of hydatid disease was chairman of the New Zealand Hydatid Research nmittee. For ten years he was also chairman of the go branch of the British Empire Cancer Campaign, he had probably done more than any other New lander in rousing public opinion to the need for ouraging cancer research. It was largely through his rts that the radium institute was set up in Dunedin.

Generations of medical graduates," writes our v Zealand correspondent, "will remember Sir Louis nett as a careful, thorough, painstaking surgeon, and indly man. He remained a pioneer, and in spite of iculties and discouragements helped to found and iblish the Otago school and the Australasian college. interest in his work persisted to the end, and I have letters, written within a few weeks of his death, nowledging and commenting on case-records of latid disease, of which he collected nearly 2000. He ained the registrar-in-chief for the college until he l, and the shaky handwriting told of a daily fight against ema. Many of his old students attended his last public earance a year ago, when he spoke once more on latid disease at the college meeting in Dunedin."

ir Louis married in 1892 Mabel Violet, daughter of Hon. James Fulton, a member of the Legislative incil of New Zealand. One of their sons, Mr. Geoffrey nett, F.R.C.S., is in practice in Dunedin.

JOSEPH SHAW BOLTON

D.SC., M.D. LOND., F.R.C.P.

Dr. Shaw Bolton, former director of the West Riding Mental Hospital at Wakefield, and emeritus professor of mental diseases in the University of Leeds, died at Beaconsfield on Nov. 12.

Born at Whitby in 1867 he was educated there at Spring Hill School and took his Inter. B.SC. Lond. while working as a pupil to the local doctor. After two years spent as an unqualified assistant in a private asylum and in a general practice in Manchester, he graduated B.SC. at the age of 21, and was able to fulfil his father's condition that he must have saved £100 before he could go to University College, London. Here in 1894 he graduated M.B. and was awarded the gold medal, Atchison scholarship, and Filliter exhibition, and the following year took his M.D. He spent three years in Birmingham as assistant lecturer in physiology before becoming pathologist under Sir Frederick Mott at Claybury, and he held the post of senior assistant medical officer at Hellingly and later at Rainhill before he was appointed to Wakefield in 1910.

On his appointment, Shaw Bolton's anatomical and physiological investigations into the cerebral functions of the brain were already well known, and he was recognised as a worthy successor to such men as Bevan Lewis, Ferrier, Crichton-Browne, and Maudsley who had made Wakefield a centre of scientific progress and research. In July, 1914, he published his magnum opus, *The Brain in Health and Disease*, which he described as an attempt to settle the question of cerebral function on the old-established bases of anatomy and physiology and of histological and clinical pathology. Appearing as it did on the eve of war the book never received the attention it deserved, for by the time the war was over a new school of psychiatry had arisen. Shaw Bolton remained its courageous and doughty opponent, and in his Myth of the Unconscious Mind (*J. ment. Sci.* 1926, 72, 25,) he expressed freely and frankly his views on the Freudian school.

"When Shaw Bolton came to Wakefield," writes M. J. McG., "he found two hospitals—one an acute or admission modern hospital opened in 1900 and the other an old building, many parts of which remained more or less as when the building was opened in 1818. His predecessor's great achievement was the building of the admission hospital, but to Shaw Bolton was left the far more difficult problem of modernising the old building and making the whole hospital one administrative unit. An active and energetic man, his policy was to get things done and not to waste time talking about them. At times indeed he got the work done first and then asked the permission of the committee, permission which was always granted, perhaps with a grumble or two. But Shaw Bolton was a Yorkshireman and had to deal with a committee of Yorkshiremen, and I think they understood and appreciated each other."

In 1910 Shaw Bolton was Goulstonian lecturer of the Royal College of Physicians, and the years that followed brought many other distinctions—Maudsley lecturer in 1925, president of the Royal Medico-Psychological Association in 1928, Henderson Trust lecturer in 1933, hon. D.SC. of Leeds in 1934, Lumleian lecturer in 1935. "But he regards them all," wrote J. K. J. in 1936, "with complacent detachment as accidents in course of loved work; he is only roused to reminiscent enthusiasm by recollections of his early battle to gain footing in a medical school, to get permission to marry as an assistant medical officer, and to establish the first university diploma in psychological medicine."

Shaw Bolton retired in 1933 but quickly re-emerged to become medical superintendent of Buckinghamshire Mental Hospital for an interregnum of six months.

S. R. T. and I. S., who joined the staff of the hospital at this time, write: "We found the temporary chief a

Parliament

FROM THE PRESS GALLERY

Winter in Germany

SPEAKING in the debate on the King's Speech Mr. A. EDEN said that, though the Government claimed that in Germany they had won a victory in the battle of last winter, it was clear that the battle of this winter would be infinitely sterner. The Lord President of the Council had told the House on May 23 that the United States government had agreed that there should not be a starving British zone in Germany side by side with an American zone getting assured supplies. Both zones should have the same standard of rationing and the same degree of assurance that their supplies should not suddenly come to an end. Now there was a desperate food crisis in our zone. How, Mr. Eden asked, did that square with the assurance which Mr. Morrison got from the American government last May? Mr. Eden could understand the food position becoming desperate next spring, but it was impossible to conceive how it could become desperate now, after a good local harvest, unless there was maldistribution, which meant bad administration.

Mr. J. HYND, the Chancellor of the Duchy of Lancaster, freely admitted that there had been delays and difficulties inseparable from a quadripartite administration. Maintenance of the present health standards of the German people, low as they were, and the regular distribution of rations, low as they sometimes had to be, had been something of a miracle. He agreed that we were facing another grim winter, but he did not share Mr. Eden's apprehensions that the battle of this winter was going to be as difficult as that of the last. He attributed the sudden excitement and publicity regarding the German food situation to two factors. First, United Kingdom reserves had run down and shipments were in arrear, so that there was no question of switching British shipments to Germany as in the past. Secondly, local-government representatives had assumed responsibility for collection and distribution of food, and, having seen the statistics, they were shocked at the situation which they had to face. Another factor in the situation was that the Government had deliberately increased the ration to 1550 calories a few weeks ago. The reason was not that we had more stocks, or more food in sight, but because the situation in Germany made that action inevitable. It would have been inhuman to expect the Germans to live, produce, or do anything whatever on 1000 calories. In spite of the difficulties, Mr. Hynd continued, they had every reason to expect at least 80% overall of the 1550 calories ration—at any rate until the end of this month. By that time he hoped that the conference with our American allies would have produced the answer. The German harvest had been quite good in the circumstances, and had produced 1½ million tons of grain, which was being collected and threshed as expeditiously as possible and consumed currently.

As to the question whether common ration standards and pooling resources would operate, and whether the agreement reached by the Lord President of the Council last March was to be operated, Mr. Hynd hoped he would not be pressed in the matter because implementation of that policy was being discussed at the present time, and unless it were carried out it would be impossible to achieve any kind of progress in the development of the British zone or British and United States zones.

Dr. BARNET STROSS felt that the world food situation could hardly be worse. He had hoped that Sir John Orr would have succeeded in his ambition to bring about a World Food Board. Today a little over half the people in the world had less than 2250 calories, less than a third had over 2750 calories. In the world at any time there were apparent food surpluses in some areas and great need and famine conditions in others. Where surpluses seemed to exist there had been no control and planning. Recent developments in America had caused despondency and disappointment. But if America threw away wilfully her opportunity of leading the world that did not mean that Britain and the Commonwealth and every other country willing to combine with us should not say that there was no reason why people should die unnecessarily when there was a food glut in many parts of the world.

QUESTION TIME

Full-time M.O.H.s

In the House of Lords on Oct. 28 Lord MERTHYR asked the Government in how many county districts in England and Wales medical officers of health were still permitted to engage in private practice; in which counties these districts were situated; and what steps were proposed to be taken to ensure that the whole country was served by full-time medical officers without further delay.

The Earl of LISTOWEL replied: There are 511 county districts in England and 111 in Wales where the M.O.H. is not restricted from engaging in private practice. All counties except three have formulated arrangements to secure that as vacancies occur doctors appointed shall be restricted from engaging in private practice. Steady progress was being made before the war in securing the appointment of whole-time M.O.H.s, but acute shortage of medical man-power interrupted the process. A number of county district councils whose proposals for full-time permanent appointments had on that account to be deferred are now putting them forward again. These proposals have to be considered in the light of changed circumstances—for example, the proposed modification in the duties of the M.O.H. under the National Health Service proposals—and in some instances it is necessary to discuss with the authorities concerned whether any alteration of the original arrangement is desirable. The Government are in full accord with the view that the employment of full-time medical officers of health throughout the country is an object to be attained with all practicable speed.

Hospital Staffs

Mr. E. A. HARDY asked the Minister of Labour whether, in view of the fact that the London Provincial Council had failed to implement the recommendations of the National Joint Council for Hospital and Institution Staffs, he would give an assurance that any decisions reached by the Provincial Council would date from the pay-week in which April 1, 1946, fell.—Mr. GEORGE ISAACS replied: The date from which any decisions of the London Provincial Council should operate would be a matter for the council. I have no authority to intervene.—Mr. HARDY: In view of the widespread complaints of shortage of hospital staffs, is the Minister aware that such staffs in this country are seething with discontent because of the failure of the National Joint Council, which was set up in 1945, and that, despite the recommendations made in March this year that it should operate from April 1, nothing has been done so far as the London Provincial Council is concerned? They have never had a meeting.—Mr. ISAACS: The council is in some difficulty as to its constitution, and I have no power to intervene, although I am exercising what little influence I possess to speed up its establishment.—Mr. A. EDEN: Is it true that this council has never even met?—Mr. ISAACS: The London Provincial Council has not met because there is an argument as to the basis of its constitution.

Continuation of Unrra Supplies

Replying to questions, Mr. E. BEVIN stated that the Government had decided not to support the continuation of UNRRA after the completion of its present programme of operations, which will last well into 1947, largely because, in their view, the problem will then be no longer one of relief. The needs of countries are not uniform and it really becomes a question of balance of payments which will have to be taken into account. The fifth session of the council adopted a resolution to go into this problem of balance of payments, and the Government, in view of their own limited resources, cannot pledge themselves to undertake any further liability except in cases of proven need.

Cereal Exports to Europe

Replying to a question, Mr. H. A. MARQUAND stated that the quantity of grain and grain products sent from the United Kingdom to all European countries was 116,400 tons in the six months ended September, 1946, of which 70,200 had gone to Germany.

Physiological Experiments on Cats at Oxford

Mrs. LEAH MANNING asked the Home Secretary whether his attention had been called to the dismissal of the appeal by a professor of physiology, Dr. E. G. T. Liddell, against his conviction for causing unnecessary suffering to cats at Oxford University; and whether he would consider withdrawing his certificate to experiment.—Mr. C. EDE replied: Dr. Liddell has not been guilty of any offence or irregularity in the performance of experiments, and after reviewing all the circumstances I have come to the conclusion that I should not be justified in withdrawing his licence. It is, however, essential that proper care shall be taken of animals kept on laboratory premises, and I am taking up with the appropriate authorities the question of improved arrangements for supervising the care of animals at the laboratory in question.

The Disabled in Industry

Mr. SIDNEY SHEPHARD asked the Minister of Labour the number of disabled persons employed in industry; and what percentage this number represented of the total employed.—Mr. GEORGE ISAACS replied: I estimate that the number of registered disabled persons in employment on Sept. 17 last was about 590,000, which would represent approximately 3·76% of the total employed population at that date. This of course understates the real percentage of disabled persons in employment, as many of them have not yet registered.

British Penicillin Production

In answer to a question, Mr. JOHN WILMOT said that the present rate of production of British penicillin is about 360,000 mega units a month. During September export licences were issued for about 149,000 mega units.

Appearing as it did on the eve of war the book never received the attention it deserved, for by the time the war was over a new school of psychiatry had arisen. Shaw Bolton remained its courageous and doughty opponent, and in his Myth of the Unconscious Mind (*J. ment. Sci.* 1926, 72, 25,) he expressed freely and frankly his views on the Freudian school.

"When Shaw Bolton came to Wakefield," writes M. J. McG., "he found two hospitals—one an acute or admission modern hospital opened in 1900 and the other an old building, many parts of which remained more or less as when the building was opened in 1818. His predecessor's great achievement was the building of the admission hospital, but to Shaw Bolton was left the far more difficult problem of modernising the old building and making the whole hospital one administrative unit. An active and energetic man, his policy was to get things done and not to waste time talking about them. At times indeed he got the work done first and then asked the permission of the committee, permission which was always granted, perhaps with a grumble or two. But Shaw Bolton was a Yorkshireman and had to deal with a committee of Yorkshiremen, and I think they understood and appreciated each other."

In 1910 Shaw Bolton was Goulstonian lecturer of the Royal College of Physicians, and the years that followed brought many other distinctions—Maudsley lecturer in 1925, president of the Royal Medico-Psychological Association in 1928, Henderson Trust lecturer in 1933, hon. D.SC. of Leeds in 1934, Lumleian lecturer in 1935. "But he regards them all," wrote J. K. J. in 1936, "with complacent detachment as accidents in course of loved work; he is only roused to reminiscent enthusiasm by recollections of his early battle to gain footing in a medical school, to get permission to marry as an assistant medical officer, and to establish the first university diploma in psychological medicine."

Shaw Bolton retired in 1933 but quickly re-emerged to become medical superintendent of Buckinghamshire Mental Hospital for an interregnum of six months.

S. R. T. and I. S., who joined the staff of the hospital at this time, write: "We found the temporary chief a most impressive yet congenial person—reddish bearded, hair en brosse, reminding one rather of Captain Kettle—obviously enjoying his return to daily clinical work with all the relish of a retired master mariner taking the bridge once again. He had the sure and confident touch that marked the school of psychiatry to which he belonged. Strong and decisive when the occasion demanded, he had a notable humility about his own painstaking and valuable contributions to knowledge. A vivid personality with a keen sense of humour, he was no stickler for outward pomp. If there was a job to be done, he would get it done in the shortest and most efficient way. He did not hesitate, for example, to take up his abode in a patient's single room off one of the wards and to use the 'office' as his dining-room, living-room, and consulting-room; for this was the simplest and most efficient way of keeping himself on the spot in reasonable comfort. Untroubled by concessions to orthodoxy, he was adaptable to an extraordinary degree, yet he never lost command of a situation, nor one iota of his dignity. His association with the Bucks Mental Hospital was brief, but it was decisive and a landmark in the history of the hospital. The visiting committee, in recognition of his services, appointed him as their honorary consulting physician, and for some years after his final retirement in 1935 he maintained active interest in the hospital and many congenial contacts with its staff."

Dr. Shaw Bolton leaves his widow with two sons and a daughter. The elder son is a doctor who played football for England, and his daughter is also a doctor.

HARRY ROBERTS

L.M.S.S.A.

On Nov. 12 death removed from our midst, at the age of 75, one of those rare members of our profession who are much more than mere doctors. Harry Roberts combined an inborn faculty for good doctoring with a clear vision of what medicine stood for in terms of the Common Health and a passionate love of Mother Earth and all the gifts she holds for her children. These were, indeed, the three aspects of his life and work—doctor, humanist, and countryman.

Harry Roberts was born at Bishop's Lydiard, in Somerset, in 1871, was educated at Taunton and Bristol, and pursued his medical studies at St. Mary's Hospital medical school, whence he qualified L.S.A. in 1895. He had married in 1892. After practising at Hayle, in Cornwall, for eight years, he moved to London, and for two years, living at Vauxhall Mansions, he dabbled in politics, being attracted to various Labour groups and causes, and becoming one of the leaders of the Tariff Reform movement. He flirted with the Fabians, whose society had been founded in 1886, and it looked as though he would forsake medicine as a career for the political arena. In 1905, however, he returned to practice at Aldgate, and, eight months later, moved to Stepney, where he became a very successful and popular general practitioner, continuing in active work there for nearly forty years.

He built up an enormous clientèle. The introduction of the National Insurance Act in 1912 brought panel patients to his surgery in flocks: in 1924 there were more than 10,000 names on his books. He was at this time helped by four assistants and by a secretariat of able women. There were always two doctors on duty, and the practice was organised to the last degree of efficiency. The Ministry of Health was wont to send inquiring Americans and others anxious to see the panel scheme in action to Stepney for an ocular demonstration.

During a long and active life Roberts's literary output was enormous. As early as 1904 he was editing Walt Whitman and Thoreau for English readers. He had published *The Sayings of Jesus* in 1903. (Forty years later he attempted something on similar lines, but more ambitious, *The Philosophy of Jesus*, written in collaboration with a medical colleague.) He began to appear in literature as a sociologist as early as 1892, three years before he qualified as a doctor, with a small book on *Population and Social Reform*. This was followed by *Constructive Conservatism* (1913) and a more serious effort, *National Health Policy*, in 1923.

Roberts's efforts to bridge the gap between academic medicine and the popular demand for help on general hygienic lines produced what was probably his most successful work, *Everyman in Health and Sickness*, published by Dent in 1935. He was arranging for a modernised edition of this book at the time of his death. *Euthanasia* appeared in 1933 and *The Troubled Mind* in 1938. His contributions on kindred lines in the journals were very numerous. As a reviewer he was in great demand, as the columns of the *Times Literary Supplement*, the *Spectator*, and the *New Statesman* testify. He was an incisive but admittedly fair critic.

The third aspect of Roberts's life and work was known to thousands who never came across him as a doctor nor realised that the "green fingers" which he possessed in all matters connected with the soil and its products were also at his command when the sick person needed him. In 1908 he built a house to his own design high up in the Hampshire "hangers," and lived here and in busy Stepney the double life with which his many friends became familiar. His books on the country life sufficiently proclaim his activities. But many years before this he had revealed this side of his nature. *The Chronicles of a Cornish Garden* and *Old Fashioned Flowers* appeared in 1901, *The Tramp's Handbook* and *The Still Room Book* in 1903. In 1915 he published *All about Gardening*. Roberts enjoyed the distinction of being the only author with two volumes to his credit in the *Britain in Pictures* series: he wrote *Rebels and Reformers* in 1942 and *English Gardens* in 1944. He was an authority on gipsies, brewed excellent cider, made large quantities of saleable pot-pourri, and knew all that could be done with the compost-heap without making a god of "humus."

He was as good a talker as writer. There were few men and women "in letters" who did not visit him at Oakshott, and his correspondents were even more numerous than his guests. He was at endless pains to avoid giving offence and was quick to redeem the lapse when it occurred. Of the "little, nameless, unremembered acts of kindness and of love" that measure a good man's life his host of friends can testify abundantly.

Roberts suffered a severe attack of congestive heart-failure in 1942. He recovered as the result of much care on the part of devoted friends. As the result of equal care he lived a fairly active life until his sudden death whilst sitting at his writing table. His was a virile, restless, and dynamic soul, but he was highly constructive and sane in his outlook and he achieved much in a field that was new when he entered it—the field of Social Medicine. When H. M. Tomlinson heard of his friend's death he said: "But he's more alive still than most of us." The comment makes a fitting epitaph for one whose spirit lives and whose work endures. H.

> ". . . Whose liberal virtues freed his fretting soul
> To see life steady and to see it whole."

So his friend Horace Horsnell wrote of Harry Roberts about the time of the 1914–18 war. It is a nutshell picture of a man as humane and rebellious as Thomas Wakley, as witty as Falstaff, as various as Cleopatra; shrewd, too, and with a gift for lifelong friendships.

Long ago he bought a beech-filled valley in Hampshire, where he and his friends used to go to camp, and to plan a house. In time they put up huts in the woods, and stayed there often. At last the imagined house began to grow, half-way between the valley and the crest of the hanger.

> At first it was like an ancient manor house—a single great room with an open fireplace—but over the years more rooms clustered about it, until, within the last decade, his sister added a bathroom. Roberts was indignant. "Now it's like anybody else's house," he complained. But it was not. Oakshott had a special quality, quite indescribable, created by Harry Roberts and those who shared it. A friendly house, full of friendly people, where the cooking was done brilliantly (Roberts was an expert, and

so were his companions) in the intervals of discussion on war, society, and art, where helpers from the village were spoken of as retainers, lest anyone should fancy them serfs, where little cats grey as squirrels blew about like smoke, and where Roberts and the good company who sought him talked, heard music, and joined—earnestly or casually—in the work of house, farm, and garden.

He was a good neighbour; the town hall at Petersfield was built largely through his efforts: and during this war he founded a local youth club, and then helped the young people to take over the full responsibility for it.

He was like no other landowner. Once he discovered in an old map a forgotten right-of-way crossing his land; he hurried out to clear the path and put up inviting notices. The other end of this path crossed the land of a farmer who was far from sharing his enthusiasm. They corresponded, and for a week the farmer was Roberts's blackest villain; then he went to see him and came back cheered and pacified. The farmer was a splendid fellow: it was true he didn't want hikers going straight through the farmyard, but was perfectly willing to open an alternative route.

This was characteristic: Roberts had only to see and talk to an opponent to recognise his good points and give generous credit for them. Implacable over principles, he was always sympathetic to persons. That is why his death has robbed so many of a great friend.

He leaves a son and daughter, three grandchildren, and two great-grandchildren. M. N. J.

NIKOLAI BURDENKO

News of Colonel-General Burdenko's death has swiftly followed his resignation, because of ill health, from the presidency of the Soviet Academy of Medical Sciences. As surgeon-in-chief to the Red Army, member of the Supreme Soviet, and director of the Moscow neurosurgical institute, he was a great figure in Soviet life as well as in Soviet surgery.

Born in 1878, the grandson of a serf, he served in a Red Cross detachment during the Russo-Japanese War and received the Soldier's Cross of St. George for bravery. In 1904 he graduated in medicine at the University of Dorpat, and four years later he was appointed to a chair there. Postgraduate work in Pavlov's laboratory followed, and during the 1914–18 war he served as a consultant surgeon, becoming chief of the Russian army medical service in 1917. In 1924 he went to Moscow with the task of establishing the first Soviet neurosurgical institute. Here he built up a strong team of neurologists who derived from Pavlov's school.

Burdenko himself specialised in the surgery of the central nervous system, and under his leadership the Army service for injuries of the brain and cord was extremely well organised, with interchangeable teams from front line, through the base hospital, to convalescence in the Far East. Among his colleagues he was especially honoured for his operations for tumours of the third and fourth ventricles and in the pituitary and posterior cranial fossa. A British surgeon who watched him operating in 1943, when his powers were admittedly already impaired by his physical disabilities, found his technique less advanced than that obtaining in the neurosurgical clinics of this country or America. But there was no doubt of the devotion, esteem, and respect which Burdenko's vital personality and stimulating teaching had inspired among the professoriate and the "young men," and of the influence he exerted on the medical profession throughout Soviet Russia. The medical service he did so much to foster accomplished great things for the Red Army.

On Active Service

CASUALTY

Flight-Lieutenant Raymond George Blackledge, previously reported as missing, has now been presumed to have died about Jan. 20, 1945, while a prisoner-of-war in Japanese hands. Born in 1912, he studied medicine at Oxford University and St. Thomas's Hospital and graduated B.M. in 1937. After holding house-appointments at St. Thomas's, the Radcliffe Infirmary, Oxford, and the Miller General Hospital, Greenwich, he was commissioned as flying-officer in the medical branch of the Royal Air Force Volunteer Reserve in September, 1940.

Appointments

Antonio, R. F., M.B. Edin.: M.O., Gold Coast.
Beal, J. R., M.D. Manc., D.P.H.: senior tuberculosis officer, Northumberland County Council.
Clouston, G. S., M.D. Lpool, D.P.M.: psychiatrist, West Suffolk and Ipswich Education Committees.
Litchfield, J. W., B.M. Oxfd, M.R.C.P.: physician i/c outpatients, St. Mary's Hospital, London.
Muir, Clement, M.B. Edin., M.R.C.P.E., D.P.H.: principal assistant M.O., Surrey County Council.
Preston, J. R., M.B. Glasg., D.P.H.: M.O.H., Sutton Coldfield.
Read, M. T., M.C., M.R.C.S.: M.O., Malaya.

London County Council Assistant Medical Officers on Central Administrative Staff:

- Austin, F., M.R.C.S.
- Cran, E. M., M.B. Aberd., D.P.H.
- Harrison, T. H., M.R.C.S.
- Peet, F. L., M.D. Durh., L.D.S.
- Thomson, R. T., M.B. Glasg., D.P.H.

Diary of the Week

NOV. 24 TO 30

Sunday, 24th

Family Planning Association
10.30 A.M. (Gas Industry House, Hyde Park Corner, S.W.1.) Conference. (1) Experience of some Local Authorities in Providing Contraceptive Advice within the Terms of the Ministry of Health Memoranda; and (2) Clinical Problems in Contraceptive Technique and the Atypical Cases.
2.30 P.M. Developments in the Treatment of Subfertility and their Application to Clinics.

Monday, 25th

Royal Society of Medicine, 1, Wimpole Street, W.1
5.30 P.M. *Odontology.* Mr. D. Greer Walker: Severe Infections of the Mandible. Prof. M. A. Rushton: Regional Osteitis Fibrosa Affecting the Facial Bones.
Medical Society of London, 11, Chandos Street, W.1
8.30 P.M. Mr. W. M. Mollison, Dr. Philip Cloake: Diagnosis and Treatment of Aural Vertigo.

Tuesday, 26th

Royal Society of Medicine
5 P.M. *Medicine.* Dr. E. B. Ford, Mr. Aleck Bourne, Dr. Kenneth McFadyean, Mr. Justice Humphreys: Birth Control: Some Medical and Legal Aspects.
London School of Dermatology, 5, Lisle Street, W.C.2
5 P.M. Dr. H. Gordon: Limitations of X-ray Therapy in Dermatology.
Edinburgh Postgraduate Board for Medicine
5 P.M. (Royal Infirmary.) Mr. D. M. Douglas: Experimental Approach to Surgery.

Wednesday, 27th

Royal Institute of Public Health and Hygiene, 28, Portland Place, W.1
3.30 P.M. Miss Barbara Low: Juvenile Delinquency.
National Hospital, Queen Square, W.C.1
5 P.M. Dr. F. M. R. Walshe, F.R.S.: Contribution of Clinical Study to the Physiology of the Cerebral Motor Cortex. (Victor Horsley lecture.)

Thursday, 28th

University of London
5 P.M. (University College, Gower Street, W.C.1.) Sir Joseph Barcroft, F.R.S.: Flora of the Alimentary Canal.
Royal College of Surgeons, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. R. W. Raven: Diseases of the Pharynx and Œsophagus. (Erasmus Wilson demonstration.)
Royal Society of Medicine
5 P.M. *Urology.* Mr. R. H. O. B. Robinson: Problems of Renal Lithiasis. (Presidential address.)
Medico-Legal Society
8.15 P.M. (26, Portland Place, W.1.) Mr. Ivor Back: Murder of Miss Gilchrist.
Middlesex County Medical Society
3 P.M. (Chase Farm Hospital, Enfield.) Cases will be shown. Mr. J. A. Dunlop: Prevesicular Prostatectomy.
Socialist Medical Association
7.30 P.M. (296, Vauxhall Bridge Road, S.W.1.) Dr. F. Avery Jones: Social Aspects of Peptic Ulcer.
London School of Dermatology
5 P.M. Dr. A. D. Porter: Vitamin A in Dermatology.

Friday, 29th

Royal College of Obstetricians and Gynæcologists, 58, Queen Anne Street, W.1
5 P.M. Dr. J. F. Loutit: Rhesus Factor.
Royal Society of Medicine
5.45 P.M. *Endocrinology.* Cases will be shown at 5 P.M.
London Chest Hospital, Victoria Park, E.2
5 P.M. Dr. J. R. B. Hern: Asthma.

Saturday, 30th

Medical Society for the Study of Venereal Diseases, 11, Chandos Street, W.1
2.30 P.M. Dr. J. A. W. McCluskie: Cardiovascular Syphilis.

In our leading article on the Artificial Kidney last week (p. 720) "plasma phæresis" should read "plasmaphæresis" from πλάσμα + ἀφαίρεσις (=removal).

Notes and News

LONDON MEDICAL EXHIBITION

THE exhibition, the first since 1938, was held this week in the Royal Horticultural Society's hall. The displays were an excellent reminder of the many war-time innovations. Medicines on a stand all look much the same; but in the various new gadgets there was much to draw the eye of the casual visitor. Plastics, as might be expected, are coming to the fore—for example, in the manufacture of stethoscopes; they are also being used for aspherical magnifying glasses, which are light and fairly cheap, and magnify three or four times without distortion over a large area, so that there is little discomfort in reading with them. For the ophthalmologist there is, too, a new rotary drum to hold trial lenses in much less than the normal compass. For eye and ear work there are droppers from which the fluid is obtained by warming the container in the grip; the number of drops is easily controlled, and the solutions are said to remain virtually sterile for at least two to three years. Then there are new devices for the liberation of penicillin and other antibacterial agents as a fine vapour into the air of ward or office. Perhaps the most interesting exhibit was a prototype electrically operated machine for the automatic control of respiration; clinical trials are reported to have proved its value in intrathoracic operations. The rhythm, rate, and depth of respiration can be readily controlled, and intrabronchial suction is possible. The machine, which is simple and light, should have a future as a resuscitator—by the sea, in the wards, and even in ambulances.

DENTAL DEADLOCK

THE Joint Advisory Dental Council has expressed its willingness to reopen discussions with the Minister of National Insurance on the fees payable for insured persons. At present dentists are doing no work under N.H.I. on the grounds that they cannot provide a satisfactory service on the fee scale offered by the Minister. In Parliament on Oct. 25 the Minister suggested that the approved societies could not afford the higher scale proposed by the Dental Council; the council does not agree with this view but is willing to discuss the point and put forward means of solving the difficulty.

A PHARMACIST'S VIEW

SPEAKING in London on Oct. 21, Mr. Hugh Linstead, M.P., secretary of the Pharmaceutical Society, said: "Running through proprietary medicine advertising there is a general disparagement of the medical profession. . . . It is a commonplace of testimonial advertising that the general medical practitioner is disparaged, and by implication the National Health Service. . . . There are at present far too many completely worthless medicines being sold to the public. I am quite certain that far too many advertisements skate on the very thin ice of creating fear. . . . I think that varying standards should all be amalgamated and the proprietary medicines industry might very well set up a council of public men . . . who . . . might be prepared to pass the proprietary medicine brought before them. I think you must have a register of medicines and makers . . . you must have a prohibition against false and fraudulent claims." Formulas, he concluded, should be laid down by the advisory committee and not by the manufacturer.

A SCIENTIFIC NEWS-LETTER

ANY publication that helps to spread the scientific outlook among general readers deserves a hearty welcome. *Science To-Day*[1] sets out to do this in a weekly news-letter of eight small pages, giving the layman the why and wherefore—not thrusting sensational items, to be gaped at as nine-day wonders, before a goggle-eyed audience. The first four pages contain news items, mostly culled from the current technical journals; the remainder are given up to a background article reviewing some larger subject of topical interest. The early issues mention such widely different topics as fish migration, radar, nuclear physics, Giacobini-Zinner meteors, penicillin, thyroid chemistry, cosmic rays, curare, gas turbines, and calculating machines. The doctor who likes to keep in touch with the growing points on the tree of knowledge will enjoy this little journal.

THE CHURCHES' COUNCIL OF HEALING

THE third of a series of lectures arranged by the Churches' Council of Healing is being given at Denison House, 296 Vauxhall Bridge Road, London, S.W.1, on Dec. 11 at 7 P.M when the Rev. J. Crowlesmith, secretary of the Methodi Society for Medical and Pastoral Psychology, will speak o Possibilities of Coöperation between Doctors and Clergy in th Healing of the Sick.

Since the purposes of this council are not generally known it may be useful to note here that the late Archbishop Temple who founded it, was deeply anxious to reconcile religion and science, and especially the practice of medicine and the practice of religion. "His chief aim" (writes a doctor interested in the work) "was to bring together the many branches of the modern divine and spiritual healing movement on the basis of an acceptance of the assured results of modern science and a belief in the value of divine healing. By this means he believed that a real unification of all the forces that make for health and healing may be achieved, and in particular that the healing work of the medical profession might be united to an equally important healing mission of the Christian Church in all its branches."

Such a synthesis of aims could hardly have been conceived much less approached, in the last century; but in modern medicine the non-physical factors are assuming increasing importance; and the materialist hypothesis, our correspondent suggests, has itself been placed on the defensive. "Doctors are asking by what philosophy they shall guide their practice. Ordinary people are asking a similar question." The movement initiated by the Archbishop aims at "integrating the humanist tradition characteristic of modern scientific medicine with the 'supra-humanist' tradition characteristic of the Christian Church. This integration seems to have been achieved without the sacrifice of the truths and values either of scientific medicine or religion. The practice of divine or spiritual healing is conceived as being the *completion* of the work of modern medicine and not as a *substitute* for it."

This interpretation of the work of the Council of Healing is in line with a resolution adopted in the Lower House of Convocation of York on Oct. 17, asking Dr. C. F. Garbett, the Archbishop, to appoint a joint committee to consider the use of psychology in the pastoral office of the clergy and "the steps needed to regularise the work of priest psychologists." The *Manchester Guardian* (Oct. 9) pointed out that this recalls a resolution passed in the Upper House of Convocation in 1938, welcoming "the movement for developing consultation and coöperation between clergy and doctors, especially medical psychologists."

SCOTTISH MENTAL HOSPITALS' PATHOLOGICAL SCHEME

THIS scheme has now become a division of the pathology department of Edinburgh University. The board's 48th annual report indicates that the change has reduced the annual expenditure under the scheme; the surplus revenue is to be made available for research to those employed by the contributing hospitals, and possibly to others.

MIDGET HEARING AID

Messrs. Amplivox Ltd., of 2, Bentinck Street, W.1, have produced a new hearing aid which they call the 'Omnipac' and which they claim is the smallest in the world. As the name suggests, the whole mechanism is compactly made up in one case from which runs the lead to the earpiece. The case measures 4 in. × 2$^1/_2$ in. × 1 in. and weighs complete with batteries 10 oz. This relatively midget size has been achieved by a new miniature valve and miniature batteries of high output. It is claimed that the low-tension battery, costing 1*s.* 6*d.*, is of revolutionary design, giving an unlimited shelf life with a life of 30 hours on continuous load, while the high-tension battery costs 3*s.*, has a shelf life of months, and lasts 100 hours on load. There is also a new type of earphone which can be used with the aid, requiring no head-band and fitting comfortably in the meatus. The performance of the aid is most satisfactory and as good as any standard valve-amplifying instrument. An additional unit can be supplied for use with a telephone which plugs into spare sockets on top of the aid. This is a useful and successful device. The instrument marks a definite advance in construction. It sells at 21 guineas, the telephone unit costing 2 guineas extra.

DELAY IN SUPPLY OF SPECTACLES

THE Faculty of Ophthalmologists recently appointed a subcommittee, on which the manufacturing opticians were represented, to investigate the delay in the supply of spectacles. It is anticipated that in twelve months the accumulation of orders which is causing the delay will have been dealt with and that deliveries will be back nearly to normal; but it was agreed that in the meantime six suggestions should be published for the consideration of prescribing surgeons and opticians. The council of the faculty believe that the adoption of these suggestions would result in an immediate improvement in the situation. The suggestions are as follows:

1. Except in cases of genuine medical urgency, avoid priority orders.
2. Unless there are good reasons for the contrary, avoid prescribing $^1/_8$ powers, and $^1/_4$ powers over 4D.
3. In the lower ranges, covering the "stock powers," prescribe *flat* lenses; except in the case of bifocals, which are more easily obtained in toric form.
4. Avoid ordering tinted lenses wherever possible. When ordered, give alternative tints.
5. Where possible, indicate on the prescription that a variation of $^1/_4$D up or down is permissible. It is suggested that this should be done by the sign " ±0·25 " on the prescription.
6. Avoid prescribing prisms unless really necessary. All prescriptions including a prism, other than those that can be dispensed by decentration, demand special grinding.

MOBILE EXHIBITIONS OF NURSING

To encourage nursing recruitment, the Ministry of Labour and National Service have launched two mobile exhibition vans, which are to visit villages and the smaller towns. The exhibition, which consists of cheerful and informative photographs of nurses in various stages of training, at work and at play, is mounted on and inside a very large trailer, drawn by a tractor on the roof of which a loud-speaker is mounted. Inside, besides more pictures, there is a small comfortable interviewing room, whose cork-lined walls are sound-proof. Here the prospective candidate for nursing can talk to one of the technical nursing officers of the Ministry, and also, thanks to collaboration promised by local hospitals, with a young nurse in training in the region. The loud-speaker microphone is in this little room, and a gramophone beneath it can be used to broadcast music. During the next month these vans will tour the southern and south-western regions, near Reading and Salisbury. In launching one of the vans on Nov. 13, Mr. George Isaacs, the Minister of Labour, noted how much thought and hard work had gone to the making of the exhibition. It should help to maintain the rise in nursing recruitment which has gone on since the beginning of the century; and if the interviews are well conducted, as seems likely, it may also help to reduce the present high wastage of recruits.

PSYCHOLOGY OF STUDY

A CORRESPONDENT signing himself "Ex-Service M.O." wrote asking advice on the best method of preparing for an examination while carrying on with a full-time job. His letter appeared in THE LANCET of August 31, p. 312. Dr. W. H. Perry now writes from Vancouver, saying: "I would refer your correspondent to a little book, *Doctor in the Making*, by A. W. Ham and M. D. Salter, of the University of Toronto, published by J. B. Lippincott and Co. It is very pleasant reading and while designed for the junior undergraduate can be very helpful to those preparing for higher examinations; particularly those of us who, on account of the recent unpleasantness, have suffered a severe and prolonged interruption of our study habits."

RADIOLOGICAL PROTECTION

THE 6th edition of the recommendations of the British X-ray and Radium Protection Committee, lately reprinted in booklet form, contains a new appendix including a section on X-ray examinations under general anæsthesia. The committee has never maintained that there are no risks in radiological work, but it has always held that these can be largely avoided by observance of its 67 recommendations. The booklet is obtainable on application to the hon. secretaries at 32, Welbeck Street, London, W.1. The Medical Research Council has lately set up a Protection Committee as a subcommittee of the Research Committee on the Medical and Biological Applications of Nuclear Physics; the main function of this committee will be to initiate research into new methods of protecting the staffs of establishments now being organised for the large-scale production of radioactive isotopes.

Royal College of Surgeons of England

At a meeting of the council on Nov. 14, with Sir Alfred Webb-Johnson, the president, in the chair, the honorary gold medal of the college was awarded to Sir Alexander Fleming, F.R.S., in appreciation of his distinguished work and particularly in recognition of his discovery of penicillin.

It was reported that the trustees of the Sir Halley Stewart trust had made a grant to the college for a research fellowship, and Mr. H. Fletcher Lunn, anatomical curator, was appointed as the first fellow. Dr. R. J. Last, anatomical curator, was elected as the first Bland-Sutton research scholar.

It was reported that the special trustees had elected Mr. F. H. Masina as a Prophit research student for the investigation of the pathology and treatment of carcinoma of the bladder.

Mr. Alan Perry (London), Sir Heneage Ogilvie (Guy's), and Mr. R. M. Handfield-Jones (St. Mary's) were elected members of the court of examiners. The Hallett prize was awarded to Mr. R. P. Melville, of the University of Sydney. H. K. Ford (Epsom College and the London Hospital) was nominated as the 54th Jenks scholar.

It was decided to hold a meeting of fellows on Friday, Nov. 29, at 5 P.M., to discuss certain aspects of the National Health Service Act.

Mr. Ian Aird, professor of surgery in the British Postgraduate Medical School, was elected ad eundem to the fellowship of the college. Diplomas of membership were granted to the candidates named in THE LANCET of Nov. 9 (p. 701) as having qualified to practise, with the exception of 5 who had previously been granted membership.

Diplomas in medical radiodiagnosis, in medical radiotherapy, and in child health were granted, jointly with the Royal College of Physicians, to the candidates named in THE LANCET of Nov. 9 (p. 701).

Society of Apothecaries

The society's gold medal in therapeutics will be presented to Sir Alexander Fleming, F.R.S., and Sir Howard Florey, F.R.S., on Thursday, Nov. 28, at 8 P.M. The presentation will be followed by a soirée.

Addison Lecture

Prof. E. C. Dodds, F.R.S., will deliver the first Addison lecture at Guy's Hospital on Monday, Dec. 2. His title is Stories of Endocrine Research. Tickets may be had from the secretary of the medical school, Guy's Hospital, London, S.E.1.

Princeton's Bicentenary

Honorary degrees were conferred on Sir Henry Dale, O.M., F.R.S., and Sir John Orr, F.R.S., at the bicentennial celebrations of Princeton University.

Public-health Teaching in Croydon

Last spring the Royal Institute of Public Health and Hygiene arranged that doctors undergoing courses of instruction in preventive medicine should attend for $2^1/_2$ days each week at Croydon, where they gain practical experience of all the departments working under the local authority.

London County Council

At its meeting on Nov. 19 the council appointed Dr. A. A. W. Petrie, the senior medical superintendent in their mental-health services, to be their medical adviser on mental health. Dr. Petrie will be seconded for part of the time from Banstead Hospital to headquarters staff to fulfil his new duties. He succeeds Dr. R. M. Stewart, who has retired.

The Basic Nursing Course

The London County Council have endorsed the resolution adopted by the Association of County Medical Officers of Health providing for a two-tier system of nurses' training with opportunities for advancement from the lower to the upper tier. The resolution which has also been endorsed by the County Councils Association (see *Lancet*, Sept. 28, p. 462) proposes that—

> There should be a basic training of two years for all nurses, some of which period should be spent in nursing the chronic sick. This training should be essentially practical.
>
> After that training, and on passing their appropriate examinations, the designation should be "Qualified Nurse."
>
> A substantial number of nurses should receive further training in order to qualify them for positions of ward sister and higher. The appropriate designations to be selected later.

The L.C.C. are reserving their views on the designations to be used and other details ancillary to the application of the principle.

Medical Sheriffs

Dr. J. Emrys Jenkins has been appointed sheriff for Breconshire, and Dr. E. Wyn Jones sheriff for Caernarvonshire.

Medical Society of London

The Lloyd Roberts lecture will be delivered on Monday, Dec. 16, at 8.30 P.M., by Sir James Chadwick, F.R.S., who is to speak on Atomic Energy.

Mass Radiography in Tasmania

The Tasmanian government proposes, with the help of mobile mass-radiography units, to have the chest of every civilian radiographed periodically—possibly once in every five years.

Edinburgh University Club of London

A reception is to be held at the May Fair Hotel, W.1, on Thursday, Dec. 5, from 6.30 to 8 P.M., in honour of Sir John Fraser, the principal. The hon. secretary is Dr. Bruce Williamson, 12, Wimpole Street, W.1.

London University Conservatives

Dr. W. J. O'Donovan has been appointed provisional chairman of the University of London Conservative and Unionist Graduates' Association, which is to hold its first post-war meeting at 11 A.M. on Saturday, Nov. 30, at King's College, Strand, W.C.2.

Congress of School and University Hygiene

This congress is to be held in Paris from June 25 to 29, 1947, under the auspices of the ministries of national education and of public health. At the congress the Société Française d'Hygiène Scolaire will propose the formation of an international association to be charged with the organisation of periodical congresses and the establishment of liaison between doctors engaged in this branch of medicine. The secretary-general of the congress is Dr. Pierre Delthil, 46, Rue de Naples, Paris, 8e.

International Congress of Military Medicine and Pharmacy

At the invitation of the Swiss Government the eleventh congress is to be held at Basle from June 2 to 7, 1947. The principal subjects for discussion are the resuscitation of the wounded, the prophylaxis of epidemics, methods of determining the concentration of hydrogen ions, the evacuation of casualties, and the contribution of the medical officer to the morale and physique of soldiers.

Contact Lens Society

The society, which is open to both medical and non-medical membership, has been formed, under the presidency of Prof. Ida Mann, for the study of contact lens work in all its aspects. The joint secretaries are Mr. A. G. Cross and Mr. G. H. Giles, to whom inquiries should be directed at 65, Brook Street, London, W.1. The first scientific meeting will be held there at 5.30 P.M. on Jan. 20.

More Scientists Needed in the United States

It will take five or more years to make up the shortage in scientists created by the war, according to Dr. Thomas Parran, surgeon-general of the United States Public Health Service. The federal government is offering fellowships to encourage doctors to engage in medical research.

B.C.G. in U.S.S.R.

A member of the tuberculosis institute of the Medical Academy of the U.S.S.R. has informed British United Press that in the past two decades about 3 million babies have been immunised against tuberculosis with vaccine of the Calmette type. Good results are also claimed with older children and adolescents; and it is stated that in protected children the incidence of tuberculosis is only a third of the incidence in children before B.C.G. vaccination was used.

Nobel Awards

The first half of the Nobel chemistry prize has been awarded to J. B. Sumner, of Cornell University, for his discovery of the crystallisability of enzymes; the second half has been awarded jointly to W. M. Stanley and J. H. Northrop, both of the Rockefeller Institute for Medical Research, Princeton, for researches into the purified production of enzymes and virus proteins.

Prescriber and Dispenser

The National Health Service Act means a 99·9% separation of dispensing from the hands of the prescriber, according to Mr. Thomas Reid, a member of the Pharmaceutical Society's council. No longer, he says, will the doctor's chauffeur, or any other unskilled person, act as a dispenser. "My own prophecy is that under the new health service the doctor will again become a competent writer of prescriptions."

Association of Industrial Medical Officers

At a meeting of the Scottish group, to be held in the Institute of Hygiene, Glasgow University, at 3 P.M. on Wednesday, Dec. 11, Prof. T. Ferguson and assistants will give a symposium on Occupational Medicine. Medical practitioners are invite to attend.

Welfare Foods

Potassium iodide is to be added to the vitamin A and tablets made for issue to expectant mothers. Each tabl will now contain potassium iodide 0·13 mg., vitamin 4000 I.U., vitamin D 800 I.U., and calcium phosphate *B.* 250 mg. In future the Ministry of Food cod-liver oil *will b* "cold-cleared," so as to improve its appearance and remove its tendency to cloud in cold weather.

New Fracture Bed

A new type of bed for patients with multiple fractures has been devised by Howard Hughes, an American pilot, who wa recently admitted to a Los Angeles hospital with multipl fractures, and burns prohibiting the application of plaster The bed has a "spinal" mattress, divided into six independen sections, each 5 in. square; these are mounted on screw-jacks worked by cranks within easy reach of the patient, who, by adjusting them, can raise or lower the sections, so that th spine is brought into any desired curvature.

Return to Practice

The Central Medical War Committee announces that th following have resumed civilian practice:

Dr. F. DUDLEY HART, 152, Harley Street, W.1 (Tel.: Welbeck 6919).
Mr. J. STEWART HESLOP, F.R.C.S., 8, St. John Street, Manchester, 3 (Tel.: Blackfriars 2166).
Dr. H. EVERLEY JONES, O.B.E., 11, Park Road West, Wolverhampton.
Dr. JOHN S. PARKINSON, 10, St. John Street, Manchester, 3 (Tel.: Blackfriars 4311).
Dr. J. GRAHAM SCOTT, 11, Wexford Avenue, Johannesburg, S. Africa.

Academician Nikolai Anichkov was last month elected president of the Soviet Academy of Medical Sciences, following the retirement of Academician Nikolai Burdenko, who has since died.

Mr. Kenneth Carter, M.P.S., has been appointed secretary of the Therapeutic Research Corporation of Great Britain.

Messrs. Burroughs Wellcome & Co. have opened an office at 18, Merrion Square, Dublin.

Births, Marriages, and Deaths

BIRTHS

BULLEID.—On Nov. 8, at Midsomer Norton, the wife of Dr. A. H. Bulleid—twin daughters.
BUTLER.—On Nov. 10, the wife of Flight-Lieutenant Kenneth Butler, M.B.—a son.
EVANS.—On Nov. 10, in London, the wife of Dr. M. L. H. Evans—a son.
EXNER.—On Nov. 10, the wife of Dr. G. G. Exner—a daughter.
GLAISHER.—On Nov. 4, the wife of Dr. C. Glaisher—a daughter.
HINDS HOWELL.—On Nov. 13, in London, the wife of Dr. A. Hinds Howell—a daughter.
HOVENDEN.—On Nov. 9, the wife of Dr. T. G. Hovenden—a daughter.
LANGTON-LOCKTON.—On Nov. 12, the wife of Dr. Philip Langton-Lockton—a daughter.
MANSON-BAHR.—On Nov. 8, at Nairobi, Kenya, the wife of Dr. P. E. C. Manson-Bahr—a son.
MARSHALL.—On Nov. 14, at Carshalton, the wife of Dr. T. S. Marshall—a son.
WYLIE.—On Nov. 14, the wife of Squadron-Leader W. D. Wylie, M.R.C.P.—a son.

MARRIAGES

WHYTE—CARRINGTON-WARD.—At Karachi, India, Lieut.-Colonel D. G. C. Whyte, D.S.O., R.A.M.C., to Patricia Carrington-Ward.

DEATHS

ALLAN.—On Nov. 7, Flying-Officer Charles King Allan, M.B. Glasg., aged 23.
BOLTON.—On Nov. 12, at Beaconsfield, Joseph Shaw Bolton, D.SC., M.D. Lond., F.R.C.P.
BROWNLIE.—On Nov. 12, at Edinburgh, James Law Brownlie, M.D. Glasg., M.R.C.P.E., D.P.H., F.R.S.E.
DANIELL.—On Nov. 10, at Brighton, Edgar Percy Daniell, M.R.C.S., aged 86.
GWYNNE-JONES.—On Nov. 15, Howell Gwynne-Jones, C.V.O., M.R.C.S.
LOMAS.—On Nov. 15, in London, Henry Lomas, M.D. Vienna, M.R.C.S., D.P.H.
LYNDON.—On Nov. 14, Arnold Lyndon, O.B.E., M.D. Lond., of Grayshott, Hindhead, Surrey, aged 85.
MURRAY.—On Nov. 13, at Wokingham, John Gawler Murray, L.R.F.P.S., aged 78.
ROBERTS.—On Nov. 12, at Oakshott, Harry Roberts, L.M.S.S.A., aged 75.
SULLY.—In November, at Durban, South Africa, Albert Max Sully, M.R.C.S., aged 81.

CARDIAC SIGNS IN YOUNG ADULTS

WITH SPECIAL REFERENCE TO FUNCTIONAL MURMURS *

GEOFFREY BOURNE
M.D. Lond., F.R.C.P.
PHYSICIAN IN CHARGE OF CARDIOGRAPHIC DEPARTMENT,
ST. BARTHOLOMEW'S HOSPITAL, LONDON

DURING the last six years I have examined a large number of young adults cardiologically at the request of three medical boards. This paper is based on a careful analysis of about a quarter of them, 308 in all, of whom 224 had normal hearts and 84 organic heart disease.

The cases were selected by the boards, which contained different medical practitioners. The extent and type of this selection clearly varied from board to board, and from doctor to doctor; so the results described are no criterion of the distribution of cases in the normal population. It is probably true, however, that the recruits referred provided a good indication of the type of case suspected by a doctor of having some cardiac abnormality.

I made a full clinical examination, followed by radiography in the anteroposterior and the right and left oblique positions. Where the pulmonary conus seemed to be unusually prominent, a barium swallow was also done, and the size of the left auricle thus carefully checked. An electrocardiogram was not taken as a routine, since it was early found that it yielded little additional information except in selected cases.

When the hearts of young people are examined, various conclusions may be reached:

(1) The heart is found to be perfectly normal both functionally and physically.

(2) A normal physical state is associated with cardiac symptoms.

(3) Though function is perfect, signs of disease are present.

(4) Both function and the physical state are clearly deficient.

The first and fourth of these possibilities do not raise any question as to the state of the heart.

The second group contains people with what is usually known as effort syndrome. Here there are definite symptoms, the most common of which are apparently due to excessive sensitivity of the heart both on the sensory and the motor side. Certain other symptoms and signs are also present which have no direct association with the heart. In effort syndrome palpitation, fatigue, and shortness of breath follow an amount of exertion which does not produce them in normal people. Further, symptoms of nervousness, sweating, and giddiness, probably of vasomotor origin, are frequent. The sweating is usually a cold sweat, affecting the body locally rather than generally. It is seen particularly in the axillæ, on the palms of the hands, and on the forehead, and is excessive. The heart in such cases is often clearly normal, except that its abnormal response to exercise and emotion easily provokes tachycardia. Vasomotor signs resulting from postural change are common, a raised pulse-rate and a lowered blood-pressure following the change in position from the horizontal to the vertical.

In the third group—a large one—signs suggesting some cardiac abnormality are present without any symptoms. This is the group in which diagnosis is often difficult but which is from the point of view of the State very important because admission to the Services or to any pensionable position is likely to involve expense, if a person with organic heart disease is accepted. These slight abnormalities, or suspected abnormalities, are the basis of this paper. They fall into certain well-defined clinical groups.

SIZE OF HEART

In the investigation of a cardiac patient the size of the heart is the most important single fact. If the heart is enlarged, it must be regarded as diseased, whether such disease is past or present. If the heart is normal in size, it may be concluded, especially in the young, that disease is probably absent. If the heart is of the small longitudinal type, well below the average, no organic disease is present.

In many excited but healthy young adults the position of the apex-beat is deceptive. This, especially in athletic individuals, is often so forcible that its position seems to be in the midclavicular line or external to it. Here accurate radiography is the only means of determining whether the heart is enlarged or not. There are two methods—a film taken at a distance of 6 ft., or measurement by orthodiagram. Of the two, the orthodiagram is probably more accurate, since it is possible to measure the heart either in systole or in diastole as desired. The commonest method is to define the outer border of the heart in diastole, both to the left and to the right, and to measure the interior diameter of the thorax on both sides at the end of an easy inspiration. The vigorously beating heart above described is found by such measurement not to be enlarged, in spite of the apparently abnormal position of the apex-beat.

HEART SOUNDS

The heart sounds described below were present in every case in young adults whose hearts were regarded as normal both clinically and radiologically, and whose blood-pressure was within normal limits. (Such functional or physiological murmurs and unusual sounds may also, of course, coexist with the murmurs of organic valvular disease.)

The heart sounds introduce many difficulties into diagnosis. Abnormalities occur in the first and second normal heart sounds, and in the presence sometimes of a physiological third heart sound. Furthermore, murmurs and adventitious sounds are very common, and these in their turn present problems.

The *first heart sound* is often muffled or impure, particularly when it is loud and when the heart is beating excitably or vigorously. It may occasionally be reduplicated. The most important single point about the first heart sound is its musical pitch. When the first heart sound is loud but low-pitched it is normal, and when the pitch is raised, approximating more to the quality of the second sound, there is suspicion of abnormality.

The *second sound* is chiefly investigated at the base of the heart. Reduplication is present fairly frequently at the pulmonary base, and is of no special significance. Such reduplication may vary with respiration, chiefly appearing during inspiration.

The *third sound* is a physiological phenomenon, but it is not very easily heard and is only present in a small proportion of cases—about 15% of my 308 cases. It is audible at the apex and is a single distant sound. It is heard after the second sound, which it follows at the same interval in any particular case. It is often more audible in the left lateral position and in the last half of expiration. It is apt to disappear during inspiration. It is more easily heard when the heart is beating slowly.

This sound is important, for it may be loosely described as a mid-diastolic murmur and may suggest mitral stenosis. The points to be emphasised are that the sound is short and detached, and that it is associated with no presystolic murmur and with no distant diastolic rumble. Moreover the first sound is of normal pitch, whereas in mitral stenosis the pitch is raised. Radiography of such patients commonly reveals a heart which is rather small than large, in which there is no increase in the size of the pulmonary conus. The third heart sound may also be heard in diseased hearts, particularly where there is ventricular dilatation secondary to hyperpiesis; in some cases of mitral stenosis; and in patients with an early stage of heart-block. In the first of these examples the additional sound is probably related to the first sound and not to the second. It has been found to coincide with auricular systole. In mitral stenosis the diastolic murmur may suggest a third heart sound, but there is usually a definite underlying distant diastolic rumble also, especially in the left lateral position. After the *first stage of heart-block, where the P–R interval is* prolonged, auricular systole may in this way become unusually audible. It is clear that the cases of third heart sound described above belong to none of these three groups.

---

* Read to the Torquay Medical Society on March 21, 1946.

MURMURS

Various murmurs and abnormal signs may give rise to difficulty in diagnosis.

Systolic Murmur.—The systolic murmur heard at the pulmonary base alone is not very frequent. There were only 6 examples in the 224 normal cases of the present series. But a systolic murmur at the pulmonary base conducted down the left border of the sternum to the apex is common, and the series contains 36 examples (16%). This murmur may be associated with a sensation which gives to the examining hand almost the impression of a systolic thrill, but radiography shows a perfectly normal heart, with no increase in size of the pulmonary conus. This murmur is louder when the subject is lying down and may be present only in this position. If, when the stethoscope is placed first at the apex (so that the apical systolic murmur is the first to be heard), the pulmonary systolic part of the murmur is louder than that heard at the apex, the murmur is unlikely to be organic in origin. The possibility of organic disease diminishes in proportion to the number of these functional murmurs present.

A systolic murmur heard at the apex alone is also common, with 25 (11%) in this series. The murmur was not conducted, and frequently was absent when the patient was standing, and often it disappeared during full inspiration.

The third systolic murmur of importance was that heard at the apex and heard even more loudly towards the axilla during inspiration only. There were 23 examples (10%) in the series. During expiration this murmur disappears, and it is therefore called a cardio-inspiratory systolic murmur. It is common in persons who also show a systolic pulmonary murmur conducted to the apex. No enlargement or radiological abnormality was found in these patients, who often had a heart of the narrow longitudinal type, obviously not organically diseased.

Exocardial Murmur.—Another common adventitious sound can be described as an exocardial murmur or rub. There were 26 cases (11%). Whether this label "exocardial" has any basis in fact is impossible to determine. One patient, however, produced some evidence suggesting this explanation; for there was a shuffling murmur which corresponded with all of the heart's movements—systole and diastole of the ventricles and systole of the auricles producing *a triple* shuffling sound. This is exactly analogous to what may be heard in pericarditis, where the sound is definitely exocardial. But in the present case the shuffling sound was eliminated by inspiration and was only heard during the last half of expiration and the beginning of inspiration. Moreover, radiography showed the heart to be perfectly normal in size and shape, and there were no symptoms indicating any diminution in normal cardiac function. This exceptional case is only of importance as presenting evidence for the exocardial basis of these murmurs.

The commonest exocardial murmur is that which is heard most loudly in the fourth space to the *left of the* sternum, and close to it. The sound is conducted to some extent towards the apex and to some extent towards the pulmonary base. There is no associated thrill and no enlargement of the heart, and as a rule the sound eliminated *during full inspiration. In about a quarter* the cases showing a harsh exocardial sound this is prese only at the pulmonary base. Though the murmur usually a loud rather harsh shuffle, occasionally the is a definite musical squeak, which also disappears o *full inspiration.*

These are the murmurs of greatest importance whic are found in normal young adults. They suggest variou organic lesions and have to be differentiated from then

DIFFERENTIAL DIAGNOSIS

The systolic murmurs must be differentiated from th murmur of mitral regurgitation. This murmur is hear both on standing and on lying down, though it is ofte louder on lying down. It is also not affected by respir tion. Further, in mitral regurgitation there is usuall some enlargement of the heart, and the character of th first sound may vary, being raised in pitch.

The systolic murmurs at the pulmonary base are common, especially when conducted to the apex, th they are unlikely to cause difficulty. When the murm *is restricted to the pulmonary base, the question of a* organic congenital defect may arise. Some of thes murmurs may indeed be due to a very minor lesion the pulmonary valve; but a diagnosis is impossibl because the interference with the normal circulation is slight as to cause neither symptoms nor signs. There is n cyanosis, clubbing, or enlargement of the right ventricle.

The *harsh exocardial murmurs to the left of the sternu* suggest chronic pericardial disease, but here again th heart is otherwise so normal that this diagnosis is unlikely Another possibility here is a very small patency in th interventricular septum; but in this condition th murmur *should be associated with a thrill and som* enlargement of the heart, and should be heard durin all phases of respiration.

The above murmurs and sounds have been full described because a clear clinical description may b the first step in elucidating clinical problems. Carefu examination is likely to confirm the separate character and qualities of these murmurs, and by separating then from one another some impetus may be given to attempt to define how they individually may be produced. I none of them has any characteristic abnormality bee seen on the X-ray screen. Since an electrocardiogra was not taken in every case, it is just possible that thi form of investigation might be helpful, though th examination of many thousands of normal people i hospital and in private practice has not provided evidenc that this is likely. Since, however, these murmur exist as clinical entities, it is necessary to define them s that their innocence may be clearly understood i individual patients.

BLOOD-PRESSURE

The final diagnostic difficulty which arises in apparently healthy young adults is that associated with the blood-pressure. This is often increased in nervous subjects, and a figure of 180/90 may be noticed. Three points are of importance in determining whether this increase in blood-pressure is nervous or not. The general behaviour of the patient is likely to give a clue to his nervous state. An associated tachycardia is nearly always present when the increase in blood-pressure is due *to nervous causes.* Radiographic measurement of the heart will show no increase whatever in size, as would be the case if hyperpiesis were constantly present. Indeed the heart may be small. The diastolic figure is of far greater importance than the systolic. If it is normal or only slightly raised, the hyperpiesis is unlikely to have an organic cause.

ASSESSMENT OF CARDIOVASCULAR SYSTEM

The most important points in assessing the state of the heart and cardiovascular system in young people are as follows:

(1) Is there any enlargement of the heart? If the heart is normal in size and shape, organic disease is unlikely. If the heart is small, organic disease is almost certainly absent.

(2) Is the first sound of normal or of low pitch? If it is low-pitched, any associated murmurs are unlikely to be due to mitral disease.

(3) Does the murmur disappear either on standing or on lying down, or does it disappear during respiration? Any murmur which disappears in this way is very unlikely to be due to organic disease.

During examination of these 308 subjects the following abnormalities due to organic disease were noticed:

Mitral stenosis (40).
Mitral regurgitation (13).
Mitral stenosis with aortic regurgitation (4).
Aortic regurgitation, almost certainly rheumatic, present alone (7).
Patency of the ductus arteriosus (2).
Patency of the interventricular septum (4).
Transposition of the viscera (1).
Coarctation of the aorta (1).
Enlargement of the heart, radiography showing a cardiac diameter of more than half of the chest diameter. The cause of enlargement not ascertainable (9).

The organic defects were present in these cases without symptoms, and often this was so even though the young man or woman was playing normal games and undertaking normal physical activities.

The murmurs of mitral disease were sometimes heard only when the patient was lying down, and in a few cases only in the left lateral position; and the diastolic murmur of aortic regurgitation was often so distant that it was difficult to detect, and the leak was so small as to cause no change in blood-pressure. On the other hand the congenital murmurs were loud and easy to pick up.

The series contained 9 cases of effort syndrome with characteristic symptoms but an organically normal heart.

SUMMARY

Of 308 Service recruits referred by medical boards for cardiological investigation, 224 had normal hearts and 84 organic heart disease.

Difficulties in diagnosis were mainly due to abnormalities in the first and second sounds, a physiological third sound, and adventitious sounds. These sounds are described and interpreted.

Another difficulty in diagnosis was an increase in blood-pressure in an apparently heathy person.

Suggestions for the assessment of the cardiovascular system are given.

"As we are actually situated today I do not think we can possibly have too great an increase in the amount of intelligence available in our society. . . . I . . . find men of high intellect . . . overpressed and overworked. . . . Yet the fact remains that we could at least in theory breed too many intellectuals. Firstly, in a society made up exclusively of, say, Aldous Huxleys, Laskis, Einsteins, or Stracheys, who would . . . perform the innumerable dull routine services necessary if our life is not to relapse into confusion? Secondly, even if you could get the necessary manual and unpleasant work done by compelling intellectuals to tackle it, this could only be achieved in an atmosphere of discontent and internal stress that would make . . . for revolution and dictatorships and oppression. Thirdly, pure intellect is perhaps not all that it is cracked up to be from the point of view of making the most successful sort of society in this world."—Mr. GEOFFREY ELEY, addressing the Eugenics Society on May 28. (*Eugen. Rev.* October, 1946, p. 133.)

ABSORPTION AND EXCRETION OF WATER

THE ANTIDIURETIC HORMONE

E. B. VERNEY
M.A., M.B.Camb., F.R.C.P., F.R.S.
SHEILD PROFESSOR OF PHARMACOLOGY IN THE UNIVERSITY OF CAMBRIDGE

(*Concluded from p. 744*)

INHIBITION OF WATER DIURESIS BY RISE IN OSMOTIC PRESSURE OF CAROTID PLASMA

The hypothesis that water diuresis is conditioned by an inhibition of secretion of antidiuretic substance by the neurohypophysis implies a prior governance of this secretion by the osmotic pressure of the arterial plasma. It was of interest, therefore, to determine the effects of a rise in the osmotic pressure of the carotid plasma on the secretion of the kidney during water diuresis.

Dogs have been used exclusively in this work. They were perineotomised to facilitate catheterisation, and each common carotid artery was exteriorised as a "carotid loop" (Van Leersum 1911). In the formation of the loop, two parallel incisions are made through the skin along the course of the carotid, the artery is enfolded within the strip of skin by suturing its edges behind the artery, and finally the outer edges of the skin incisions are approximated by a row of sutures deep to the tunnel of skin through which the carotid artery is now passing. During this surgical procedure the carotid sinus has sometimes been denervated, sometimes not. The animals were trained to lie quietly on their right side for long periods, and during an experiment the urine was collected continuously into a series of graduated glass tubes. The solutions for injection were carefully filtered and sterilised beforehand, and the injections were made under aseptic conditions as uniformly as possible with the aid of a beating metronome.

Effect of Intracarotid Injections of Hypertonic Solutions of NaCl.—It was first necessary to see whether intracarotid injection of isotonic solutions at different temperatures and intravenous injections of hypertonic solutions produced any effect on the course of urine flow. They were found not to do so. When, however, hypertonic solutions were injected into the carotid, definite inhibitory responses were observed (fig. 15). The magnitude of the response varied with the tonicity of the solution at constant rate and period of injection and with the period of the injection at constant volume and tonicity of solution.

Disappearance of Effect after Removal of Posterior Lobe.—The shape of these responses suggested that they were of pituitary origin, and this hypothesis was put to the test of experiment by measuring the responses to a given injection before and after removal of the posterior lobe. Fig. 16 shows that the response to 21 c.cm. of 2·50% NaCl injected into the right carotid in 20 sec. equates closely with the response to 1·0 mU of postpituitary extract injected intravenously, whereas the response to the same intracarotid injection after removal of the posterior lobe is very much reduced in size. It is, therefore, a valid procedure to assay the responses in terms of postpituitary extract; and, when this is done, it is found that the response to a given intracarotid injection is diminished by some 90% as the result of removal of the posterior lobe. It will be recollected that the response to emotional stress suffered a similar reduction in magnitude as the result of a similar procedure. No difference was detected between the response to an intravenous and that to an intracarotid injection of postpituitary extract.

Effect of Short-period Injections is Osmotically Determined.—It now became of interest to inquire whether it was indeed the increase in the osmotic pressure of the plasma which was operative in eliciting the response to intracarotid injections, and to this end comparison was made of the effects of isosmotic solutions of NaCl and

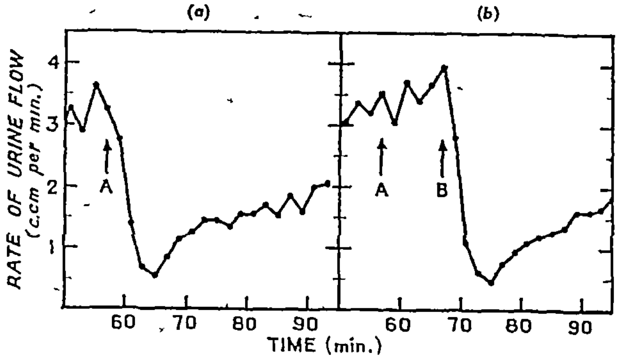

Fig. 15—Inhibitory response to intracarotid injection of hypertonic solution: (a) at A, injection of 10 5 c.cm. of 1 50% NaCl into left carotid in 9 sec.; (b) at B, injection of 11 0 c.cm. of 1·50% NaCl into right carotid in 13 sec.

dextrose. Fig. 17 shows three responses: to 10 c.cm. of 2·50% NaCl injected in 12 sec.; to 10 c.cm. of 15·4% dextrose injected in 11 sec.; and to 2·0 c.cm. of 8% NaCl injected in 10 sec., the volume and strength of this last solution being such as were calculated, at an estimated carotid blood-flow of 2·5 c.cm./sec., to produce about the same increase in osmotic pressure as the two isosmotic solutions. The three responses are indistinguishable and are all assayed at 2·5 mU. The response, therefore, is due not specifically to NaCl but to the rise in osmotic pressure.

The osmoreceptors,‡ wherever they may be, do not accommodate during short-period exposure to a rise in the osmotic pressure of the carotid plasma produced by NaCl, doubling the period of exposure to the same rise causing the release of at least double the quantity of antidiuretic substance. This lack of accommodation would be expected on the view that the osmoreceptors are continually engaged in controlling the antidiuretic function of the pituitary.

Effect of Intracarotid Infusions of Hypertonic Solutions of NaCl, and its Quantitative Assessment in Terms of Postpituitary Extract.—I will now refer to the results of longer periods of exposure to smaller increases in osmotic pressure. The infusions of the solutions of NaCl were made by means of a synchronous motor connected by reduction gearing to the head of a micrometer screw whic moved forward the plunger of the all-glass syringe wit which the fine infusing needle was connected. It wa first necessary to determine the course of the aortic blood-chloride during the infusion of a hypertonic solution (1) the left carotid artery, and (2) the malleolar vein. Chloride determinations on samples of blood from the right carotid artery taken at intervals during the 10-min period of such infusion showed that the aortic blood-chloride followed exactly the same course, irrespective of whether the infusion was made into the left carotid artery or into the malleolar vein. So far, therefore, as the effects of an increase in the aortic blood-chloride are concerned, intravenous infusions may be used a controls of intracarotid infusions.

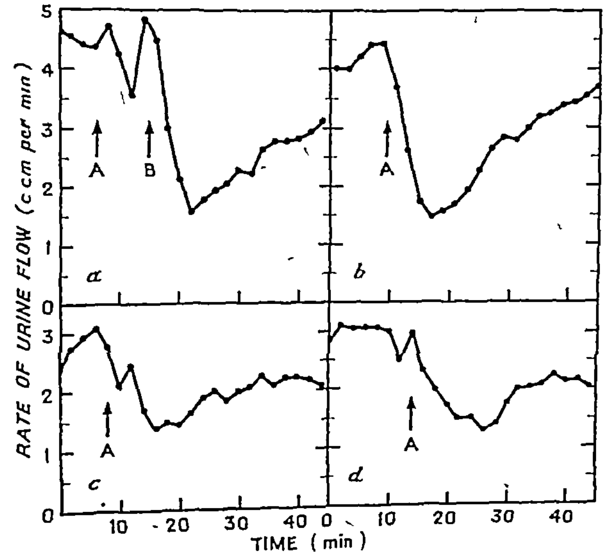

Fig. 16—Responses to injections: *a* and *b* 5 days before, *c* and *d* 11 days after, removal of posterior lobe of pituitary. *a*: at B, injection of 21 c.cm. of 2 50% NaCl into right carotid in 20 sec.; *b*: at A, 1·0 mU of postpituitary extract injected intravenously in 15 sec.; *c*: at A, injection of 21 c.cm. of 2 50% NaCl into right carotid in 20 sec.; *d*: at A, 0·1 mU postpituitary extract injected intravenously in 20 sec.

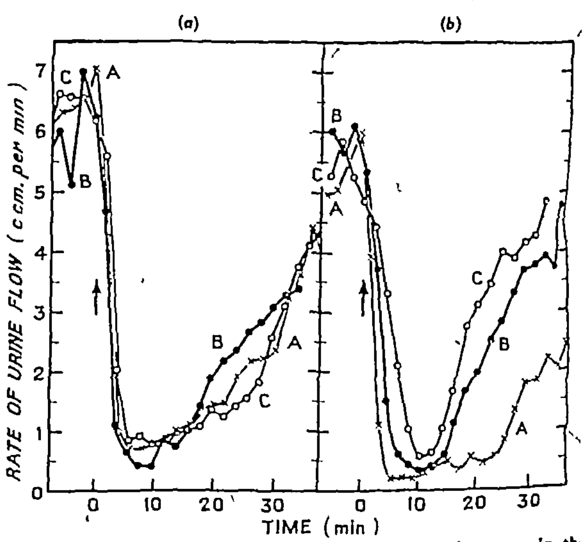

Fig. 17—Similarity between responses to equivalent increases in the osmotic pressure of the carotid plasma: (*a*) at the arrow 10·0 c.cm of 2 50% NaCl was injected into the right carotid in 12 sec. (graph A) 10·0 c.cm. of 15 4% dextrose in 11 sec. (graph B); and 2·0 c.cm. o 8·00% NaCl in 10 sec. (graph C); (*b*) at the arrow postpituitar extract 3 0 mU was injected into the malleolar vein (graph A), 2·0 m (graph B), and 1 0 mU (graph C).

Now, it was found that, when an infusion of NaC was made into the carotid over a period of 10 min., th urine flow was inhibited earlier than when the sam infusion was made into the malleolar vein; and tha as the strength of the infused solution was reduced, thi difference became greater. The cause of the earlie onset of the inhibition when the infusion was made int the carotid artery must be attributed to the increase i osmotic pressure of the blood in the vascular bed supplie by the carotid over and above that of the aortic blood Experiments were then performed in which NaCl wa infused over periods of 40 min. at the slow rate of 0 33 mg of NaCl per sec. (fig. 18). The infusion into the carot was accompanied by a gradual fall in urine flow fro 6·0 to 0·5 c.cm./min., at which level the flow was persistin when the infusion was stopped. The *flow* then slowl increased to reach a rate of nearly 4 c.cm./min. thirty minutes later. The responses to intravenous infusion o the same *solution of NaCl without* added postpituitary extract, and with increasing additions of this substance are also shown in fig. 18; and the response to the intra carotid infusion is assayed as equivalent to that of an intravenous infusion of 1 µU of postpituitary extract per sec. ($0{\cdot}5\times10^{-9}$ g./sec. in terms of the standard powder). This, then, may be regarded as the rate at which the antidiuretic *substance* is being continuously secreted in the non-hydrated dog, a figure which agrees well with the results of Shannon's (1942) experiments on replacement therapy in the dog with diabetes insipidus. The carotid blood-flow of the animal *to which* fig. 18 relates is probably about 2·5 c.cm./sec. On this assump-

---

‡ The term "osmoreceptors" is used without prejudice to any specific permeability which they may later be shown to exhibit to their ionic and molecular environment.

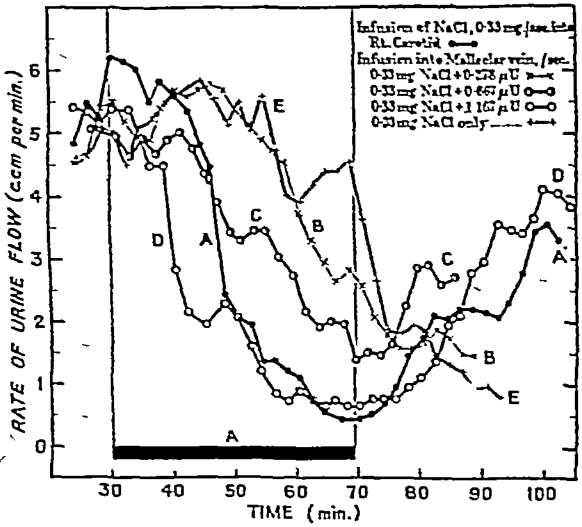

Fig. 18—Effect of prolonged infusion of NaCl into the carotid, and the method of its assay. The black rectangle covers the period of the infusions.

tion the increase in blood-chloride to which the osmoreceptors are responding and causing the pituitary to secrete 1 µU per sec. is 8 mg./100 c.cm., or, in terms of the resultant increase of osmotic pressure in the water phase of the blood, 96 mm. Hg—i.e., an increase of less than 2%. This change in blood-chloride is well within the range of the falls reported in water diuresis in man—Priestley (1921) found a fall of 35 mg./100 c.cm. of venous blood—and the smallness of the figure gains additional interest when it is recollected that the carotid infusion was unilateral.

HORMONAL CHARACTERISATION OF POSTPITUITARY ANTIDIURETIC SUBSTANCE

The recovery of urine flow when the intracarotid infusion is stopped shows that the secretion of pituitary antidiuretic substance is being inhibited by the fall in blood-chloride and consequent depression of activity in the osmoreceptors. The progression of this recovery is to be attributed to the gradual destruction in the kidney, and perhaps in the blood, of the quantity of antidiuretic substance which was maintaining the secretion of urine at a non-diuretic level. The latent period between the peak of the water-load curve and the maximal rate of urine secretion, to which I referred earlier and promised to return, is to be attributed to the same process, as indeed was foreseen at the time that work was done. Water diuresis, then, may be fitly and accurately described as a condition of physiological diabetes insipidus; and there can be little doubt that the antidiuretic secretion of the neurohypophysis is a hormone in the physiological sense, its liberation being continuously governed by the contemporary concentration of chloride, and possibly of other osmotically active substances, in the arterial plasma.

The presence of osmoreceptors connected by nerve paths with the pituitary was postulated by Klisiecki et al. (1933), who gave also references to earlier work on water diuresis. Their apprehension has now become justified; their localisation is for future inquiry. We do not yet know whether the osmoreceptors lie in the vascular bed —e.g., the supra-optic nucleus—supplied by the internal carotid artery or in that supplied by the external; they are not in the carotid sinus. Should the site of the receptors become experimentally definable, one may predict the possibility of developing a suitable technique for their exposure in the non-diuretic animal to a local *fall* in osmotic pressure, and so of producing a condition of diabetes insipidus which, in its experimental reversibility, would exhibit the attribute which theory demands.

POSTSCRIPT

Since this lecture was delivered, short-period (10 sec.) intracarotid injections of hypertonic solutions of sucrose have been found to release approximately the same amount of the antidiuretic hormone as do similar injections of isosmotic solutions of NaCl and of dextrose. A similar injection of an isosmotic solution of urea is, however, entirely without action. Moreover, long-period (40 min.) intracarotid infusion of dextrose, producing a local increase in blood-sugar of some 80 mg./100 c.cm. and the same increase in osmotic pressure as does the NaCl in the experiment illustrated in fig. 18, has no apparent influence on the course of water diuresis. It appears that, as judged within the compass of these periods, the osmoreceptors are freely permeable to urea, less freely permeable to dextrose, and relatively impermeable to sodium chloride. Further, in connexion with the localisation of the osmoreceptors, it has been found in the one animal to which the test has so far been applied that the antidiuretic response to an intracarotid injection of a hypertonic solution of NaCl vanishes as the result of ligation of the *internal* carotid artery.

ORAL PENICILLIN IN GONORRHŒA

S. R. M. Bushby
M.Sc. Brist.
OF THE WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES, BECKENHAM

A. H. Harkness
M.R.C.S.
MEDICAL OFFICER IN CHARGE OF VENEREAL DISEASES DEPARTMENT, ST. PETER'S HOSPITAL, LONDON

It was early observed by Abraham et al. (1941) that the dose of penicillin clinically effective parenterally was ineffective orally, and that the proportion of oral penicillin recovered in the urine was low compared with that of parenteral. Penicillin being unstable at low pH, its destruction in the stomach was assumed to play an important part; and the later discovery of the production of penicillinase by coliform organisms seemed to justify the view that the antibiotic could not be effective by mouth (Chain and Florey 1944).

The largely theoretical concept of destruction of penicillin by gastric juice has been thoroughly investigated.

Cutting et al. (1945) made extensive tests with enteric coatings and concluded that a resin-cellulose plastic was superior to all others, but they also incorporated acid-neutralising buffers.

Burke et al. (1945) used a double gelatin capsule hardened in formaldehyde and alcohol and gave prior treatment with aluminium hydroxide.

György et al. (1945) used sodium citrate as a buffer, and Charney et al. (1945) showed that after the *oral administration* of penicillin with sodium citrate, especially after meals, the amount of penicillin excreted in the urine was increased.

McDermott et al. (1945) combined penicillin with peanut oil as a protection against acid.

TABLE I—SERUM-PENICILLIN LEVELS AFTER ADMINISTRATION OF SINGLE DOSES OF UNCOATED AND ENTERIC-COATED TABLETS

Volunteer	Dose of penicillin (I.U.)	Tablet	Serum-penicillin level (I.U./ml.) at hours after administration			
			0·5	1·5	3·0	5·0
A	40,000	Uncoated	0·06	0·125	0·03	0·02
		Coated	<0·02	<0·02	0·12	<0·02
B	40,000	Uncoated	0·04	0·2	0·03	<0·02
		Coated	<0·02	<0·02	0·03	<0·02
C	60,000	Uncoated	0·04	0·08	0·04	<0·02
		Coated	<0·02	<0·02	0·04	<0·02
D	60,000	Uncoated	0·04	0·16	0·08	<0·02
		Coated	<0·02	<0·02	<0·02	<0·02
E	60,000	Uncoated	0·06	0·2	0·04	<0·02
		Coated	<0·02	<0·02	0·08	<0·02
F	60,000	Uncoated	0·12	0·12	0·16	<0·02
		Coated	<0·02	<0·02	0·08	<0·02

Most authors claim some advantage for their adjuvant, but Bunn et al. (1945), after a trial of antacids and suspensions in oil and beeswax, could find no instance in which their effect was superior to that obtained with penicillin either in capsule or dissolved in saline.

The present position is summed up by Finland et al. (1945), who conclude that penicillin in water gives as good results as when taken with buffers or stabilisers, though aluminium hydroxide may have a slight adjuvant effect. It seems, however, of paramount importance for penicillin in water to be taken before meals.

In the absence of experimental evidence derived from penicillin absorption and excretion-balance experiments in man, two further possibilities should be considered. Free et al. (1945) believe penicillin to be destroyed in the tissues. A contrast is drawn between the sudden flooding of the blood-stream after intravenous or intramuscular injection and the continuous entry into the circulation after oral administration. The other possibility is that penicillin is slowly and incompletely absorbed. If this is true, there may be unexpected advantages in the oral route in the case of highly susceptible organisms located in tissue other than blood.

In infections due to the gonococcus or to the pneumococcus, both of which are known to be extremely sensitive to penicillin (Ross et al. 1945), a good deal of evidence exists that penicillin may be administered effectively by mouth provided the dose is adequate.

György et al. (1945) treated successfully 18 cases of gonorrhœa in adult males, 5 cases of gonococcal vulvovaginitis in children, and 3 cases of gonococcal conjunctivitis in infants with penicillin by mouth in doses varying from 10,000 units three-hourly or four-hourly in children to 15,000–40,000 units three-hourly in adults for two or three days. In 3 further cases of gonococcal vulvovaginitis there was a relapse after three courses of the same dosage, but permanent cures followed the same dosage given intramuscularly.

Finland et al. (1945) report 7 failures in the treatment of 61 cases of acute gonorrhœa, using a total dosage varying between 120,000 and 800,000 units given hourly or two-hourly.

Ross et al. (1945) treated successfully 8 cases of gonococcal vulvovaginitis in children with four doses each of 100,000 units three-hourly. In a preliminary trial there were failures with two doses and three doses each of 100,000 units.

Cutting et al. (1945) reported 11 failures in the treatment of 53 cases of gonorrhœa. In 4 of the failures the patients had each received doses of 25,000 units, with a total dosage of 250,000 units, and in the remaining 7 failures the patients had each received doses of 50,000 units, with a total dosage of 500,000 units.

Free et al. (1945) treated 14 cases of gonorrhœa with 1,600,000 units in two days (100,000 units two-hourly during the waking period); there were no failures.

Bohls et al. (1946) treated 10 cases of gonorrhœa with one oral dose of 100,000 units, with 4 failures; 15 with a single dose of 200,000 units, with 1 failure; 13 with 100,000 units twice daily for two days, with 3 failures; and 36 with 200,000 units twice daily, with 1 failure.

The present report concerns 62 cases of gonorrhœa treated orally with six doses of penicillin 40,000 I.U. and sodium citrate 1 g. three-hourly. After single doses of 40,000 or 60,000 units (2 or 3 tablets each containing calcium penicillin 20,000 I.U. with sodium citrate 0·5 g.) taken an hour after breakfast, estimates were made at intervals on volunteers. Food, consisting of bread and butter and tea, was taken about two hours after the penicillin, and a light lunch two hours later. The resulting concentrations are shown in table I. When given in uncoated tablets penicillin appeared in the blood within 30 min., reached a peak in about 1½ hours, and was undetectable at 5½ hours. When given in tablets coated with a multilayer enteric coating of proved efficiency penicillin did not appear in the blood until after 2½ hours, and was undetectable at 5½ hours. Only 11 patients received coated tablets.

DETERMINATION OF PENICILLIN IN BLOOD

The usual methods for determining penicillin in blood serum will not detect quantities less than 0·02 unit per ml. American workers (cited by Suchet 1945) consider that lower levels than this are therapeutically effective in gonorrhœa; this may be true, for many organisms are definitely sensitive to lower levels when tested in vitro with suitable bacteriological media.

The limiting factor is the need to dilute the serum to make it a suitable medium for the growth of the test organism. Attempts to increase the sensitivity of the estimation by using the gonococcus for this purpose failed, since it grows feebly in 50% serum, and any increase in sensitivity which is gained is defeated by the need for higher dilutions. We have found Fleming's (1943) slide technique an easy and convenient method for small quantities. It avoids the need for absolutely sterile samples, as neat serum and red cells do not readily grow the ordinary contaminants, though readily allowing the growth of the test organism—a virulent hæmolytic streptococcus.

The neat blood does, however, slightly decrease the antibiotic action of the penicillin; hence levels below 0·02 unit per ml. cannot be detected. Abraham and Duthie (1946) found that penicillin was most active at pH 6·5, and by increasing the hydrogen-ion concentration of the blood we have attempted, unsuccessfully, to increase the sensitivity of Fleming's method.

PRELIMINARY OBSERVATIONS

Preliminary observations were made on patients with acute gonorrhœa treated with penicillin 40,000 units and sodium citrate 1 g. at various intervals and for various periods. There was a good response in 6 patients receiving six doses four-hourly and 6 receiving five doses four-hourly. Among 10 patients receiving four doses three-hourly and 4 patients receiving three doses four-hourly there was 1 failure in each group; both responded well to a second course of six doses three-hourly. These clinical observations suggested to us that twelve hours was too short a period of treatment, and four hours too long an interval between doses; so we decided to treat further cases (62 in all) with six doses three-hourly.

The serum-penicillin levels were determined in 53 cases. Considerable variations were found before each dose, not only from patient to patient but also in the same patient. Examples are shown in table II.

TYPE OF CASE

In this series we treated a total of 85 adult males (84 with gonorrhœa and 1 with primary anorectal gonococcal infection) and 3 adult females (1 with urethritis and cervicitis and 2 with cervicitis only). Of these 88 cases 40 were sulphonamide-resistant, of which 2 were complicated by acute epididymitis, 1 by acute prostatitis, and 3 (2 males and 1 female) had not responded to intramuscular injections of penicillin administered elsewhere. Of these latter, 1 male had had one injection of 150,000 units in peanut oil and the other had had five daily doses of 100,000 units each; the female had had one injection of 200,000 units in peanut oil and beeswax, and, owing to failure, had had a similar dose five days later. To facilitate the taking of blood two-hourly in certain patients, 42 were admitted to hospital for twelve hours and 46 continued with their usual occupations. Fluids were restricted to $1^1/_2$ pints during treatment, and there was usually at least an hour's interval between the taking of tablets and solid food. Urination took place two-hourly, immediately after the taking of smears and cultures.

CLINICAL OBSERVATIONS

A feeling of well-being during treatment was observed (as it is after parenteral administration) in many of our cases; we attribute this to the elimination of a gonococcal bacteræmia.

The gonorrhœal discharge, often more profuse 2–6 hours after the start of treatment, became progressively less during treatment; in a few cases it disappeared entirely. In a large proportion of cases the creamy discharge at the fourth hour became mucopurulent, and at each subsequent examination more mucoid, persisting as such until 2–5 days after the last dose of penicillin. Residual non-gonococcal urethritis (more frequent in sulphonamide-resistant cases) in most cases was due, as it is with parenteral penicillin, to resolution processes in gonococcal lesions, such as soft infiltrations and infections of glandular tissues. Pre-existing lesions of the urinary tract may also be a cause of persistence of non-gonococcal urethritis. This was so in one of our cases in which a discharge was present until the fourteenth day, when urethroscopy revealed a stricture of the urethra due to a previous attack of gonorrhœa.

* These figures indicate hours after start of treatment.
† These figures indicate hours after last dose of penicillin.
+ = Gonococci in films of discharge.
− = No gonococci in films.

Primary mixed infections due to both the gonococcus and non-specific organisms are also occasionally responsible for residual non-gonococcal urethritis. Penicillin is effective in destroying the gonococcus but usually does not benefit non-specific infections. One such patient (who admitted masturbation) developed an acute non-specific epididymitis four days after the completion of treatment.

The *urine*, in recent infections, still contained a few mucous threads in the first glass after completion of treatment, but in some of the older infections, especially sulphonamide failures with gross involvement of the posterior urethra, it was still muddy, or clear, with heavy threads, usually in one glass, but on four occasions in two glasses. The persistence of a mucoid non-gonococcal discharge did not often indicate the condition of the urine, as in many such cases the first morning specimen was clear, with no threads. Threads in the urine were often present for a week and sometimes for longer periods, and would no doubt have disappeared more rapidly with a few urethrovesical irrigations, withheld entirely in this series for fear of masking gonococcal relapse.

Dysuria, noted in 39 cases before the start of treatment, invariably disappeared during treatment, but in 4 cases (2 associated with painful erections, no discharge, and clear urine with no threads) it persisted two days and may have been due to restriction of fluids during penicillin therapy. The early clinical cure in the cases with painful erections was considered to be explained by the fact that resolution was taking place in structures —e.g., corpora cavernosa—isolated from the urethra.

TOXIC MANIFESTATIONS

An urticarial eruption developed in one patient two hours after the fifth dose. The sixth dose was taken, and the patient was not seen by one of us until four hours later, when there was swelling of hands, feet, and neck, and a generalised papular urticaria. Ephedrine gr. $^1/_2$ was given six-hourly, and the skin returned to normal in thirty-six hours. Before the administration of oral penicillin the patient had been treated elsewhere with several courses of sulphonamides and was said to have had, a week before seeing us, a daily injection of penicillin 100,000 units for five days. This we rather doubted, as the urethral discharge had not improved. A patch test carried out two months after completion of treatment was completely negative. This patient was reinfected a fortnight after the patch test, and no toxic manifestations were observed with a repeated course of oral penicillin.

BACTERIOLOGICAL EXAMINATIONS

Smears of the urethral discharge were examined every two hours during treatment in most cases. Giant forms of gonococci (first observed by one of us in January, 1944) were present in all cases at two hours, usually at four hours, and occasionally at six hours (their delay in disappearance being invariably associated with the use of coated tablets), when they were detected only after a thorough search. Gonococci, normal in size and shape, were also seen in most cases at two hours and often at four hours. Cultures were carried out two-hourly in many cases, but the gonococcus was not grown after smears had become negative. The rate of elimination did not appear to be related to the blood-penicillin level (table II), and the invariable presence of giant forms in smears taken two hours after the start of treatment showed that penicillin was present in the discharge at that time. The presence of giant forms in smears did not indicate that viable gonococci were no longer present in the secretions, since cultures in such cases were occasionally positive. Cultures were positive in several cases up to six hours, when coated tablets were given, after the start of treatment but never later, in spite of the presence in smears of an occasional giant form. It is an easy matter to overlook giant forms at and after the sixth hour, as they may stain very lightly and, when engulfed in degenerated polymorphs, may be mistaken for a portion of the nucleus.

TESTS FOR CURE

Our investigations began in February, 1946, and a large majority of our cases have been under observation five or six months, none less than two months. During the first fortnight examinations were carried out thrice weekly, and subsequently weekly. All patients were requested to refrain from micturating for at least three hours before each visit, when smears and cultures were taken and the condition of the urine assessed by the two-glass test.

No instrumentation or rectal investigations were carried out until fourteen days had elapsed, when in all cases there was no discharge and the urine was clear, with no threads, at which stage tests for cure were made. Anterior urethroscopy was performed. Smears and cultures after massage of prostate, vesiculæ seminales, and Cowper's glands were made on two occasions at an interval of a week. At least one of the examinations took place before the first morning micturition and usually followed the anterior urethroscopy. Other than the detection of 1 case of urethral stricture, these tests were negative in all cases. The Wassermann and Kahn reactions were negative in all cases, and the gonococcal complement-fixation reaction was positive in 8; 3 of these became negative during the period of observation, the others remaining persistent positives. The significance of these latter has been discussed elsewhere (Harkness 1944 and 1945) and is due, in our opinion, to delay in the start of treatment or to previous long-standing infection. All the failures and reinfections had negative reactions.

On completion of the above-mentioned tests the taking of alcohol was permitted, and during the subsequent observation periods of weekly examinations the Wassermann and Kahn tests were repeated on several occasions in view of the dangers of a concomitantly acquired syphilis.

FAILURES AND REINFECTIONS

In all there were 4 failures and 2 reinfections. There were 2 relapses (twenty-four hours after three doses of 40,000 units four-hourly, and forty-eight hours after four doses of 40,000 units three-hourly) during the preliminary observations, when the minimal effective amount of oral penicillin was being studied. The 2 other failures (our only failures in 62 cases receiving six doses of 40,000 units three-hourly) could be attributed to maladministration on the part of the patients. One was a labourer who had previously been resistant to one injection of 150,000 units in peanut oil and beeswax and a five-day course of sulphathiazole 1 g. six-hourly and who, owing to a misunderstanding of our orders, took large amounts of fluids during his oral penicillin course. The other was a young man who did not take the tablets at the proper intervals. Cure in both these cases was effected by a second course; the dose was, however, probably needlessly increased to 60,000 units. The case of epididymitis which developed four days after completion of treatment, when there was no discharge and the urine was clear, with no threads, was considered to be due to the effects of trauma by masturbation on a recently inflamed urogenital tract with a mild residual non-gonococcal infection. A laboratory report of the centrifuged deposit of urine showed only an occasional leucocyte, and cultures were sterile. The reinfections occurred in 2 males (who admitted exposure without protection two and three days before the onset of urethritis) a month and two and a half months after cures had been effected with six doses of 40,000 uni three-hourly; both were again successfully treated wi the same dosage.

DISCUSSION

The practical demonstration of the efficiency of o penicillin emphasises the importance of dosage. T first assumption following the demonstration that mo was required was that much was destroyed, but rece evidence gives less and less support to the theory gastric or penicillinase destruction. Our own eviden that the only effect of an enteric coating of prov efficiency was to delay the arrival of penicillin in t blood-stream gives no support to the theory of destructi in the stomach. There remains the theory of destructi in the tissues. We believe the evidence of renal clearan following intravenous and intramuscular exhibiti to obscure the field; more diffuse penicillin penetrati in tissues other than blood may well follow the slow absorption of oral penicillin. That penicillin absorpti from the gut is slow and probably incomplete is t explanation we favour.

There were 2 failures in our 62 cases treated for fiftee hours with 240,000 units (40,000 units at three-hourl intervals), a relapse-rate comparing very favourabl with our work and the work of others with parenter penicillin. An analysis of our estimates of serum penicillin levels shows the levels to have been generall at or under 0·02 unit throughout the course of trea ment. This level is lower than that quoted as essenti to success by some authorities. Thus Jones et a (1945) consider that a high percentage of cure cannot b obtained unless the serum inhibition is present in dilution of not less than 1 in 8 and is maintained for nin and a half hours; but their published figures do n support this view. This degree of serum inhibitio would necessitate a concentration of 0·08 unit per ml. and, even though most of our cases had levels higher tha this during treatment, the average level was lowe On the other hand, some American workers maintai that blood-penicillin levels undetectable by laborator methods are clinically efficient, and Allan (1946) is of th opinion that a demonstrable amount of penicillin in th blood need not be maintained so long as hitherto believe necessary, nor that the level need be high. Perhap further study of different serum-penicillin levels main tained for different lengths of time will explain thi discrepancy. Jones et al. (1945) believe 0·08 unit fo nine and a half hours to be essential; we maintained level of about 0·02 unit for about fifteen hours. Ou figures support the view that lower serum-penicilli levels maintained for a longer time may be effective since we had 2 failures in 14 cases receiving nine hours treatment, and only 2 failures in 62 cases receivin fifteen hours' treatment. Again, the presence of gian forms of gonococci before penicillin has been detecte is evidence of antibiotic activity at low serum-penicilli levels.

Non-gonococcal urethritis persists for various period with equal frequency, after successful oral and parentera penicillin therapy, but in our opinion it occurs mor often than after successful sulphonamide therapy. Adjuvant treatment, consisting of urethrovesical irrigations, would have been helpful in aiding resolution in some of our cases and is recommended, but it was withheld for fear of masking gonococcal relapse.

The minimum of interference until fourteen days after the disappearance of gonococci from the secretions is a wise precaution, as trauma due to instrumentation and prostatovesicular massage may precipitate local or metastatic non-gonococcal complications; in one of our cases epididymitis followed masturbation.

Oral administration of penicillin incorporated in sodium citrate is recommended for the treatment of gonorrhœa. It is necessary, however, to give a word of warning on the importance of regular dosage during the fifteen hours' course; otherwise failure may sometimes follow, as it does with sulphonamide therapy. Short concise instructions should be given verbally and in writing to each patient. The course of treatment has the advantage that the drug is taken only during fifteen normal waking hours.

SUMMARY

Of 62 cases treated for fifteen hours with six doses each of penicillin 40,000 units and sodium citrate 1 g. given by mouth, a total of 240,000 units, 2 cases relapsed.

This rate compares favourably with our experience of parenteral therapy.

It is important to keep strictly to the regular dosage schedule and the restriction of fluids to 1½ pints during the course.

We are indebted to Dr. P. Lamb, of St. Peter's Hospital, and to Mr. A. E. Day and Mr. J. Croxford, male nurses at St. Charles's Hospital, for their collaboration; and Messrs. Burroughs Wellcome & Co. for supplying the tablets, each containing calcium penicillin 20,000 I.U. and sodium citrate *0·5 g.*

HÆMOPOIETIC RESPONSE TO FOLIC ACID IN PERNICIOUS ANÆMIA

THE STERNAL-MARROW CHANGES

R. J. HARRISON
M.R.C.P.

J. C. WHITE
M.B. Birm.

From the Departments of Medicine and Pathology, British Postgraduate Medical School, Hammersmith

THIS paper describes the results of folic-acid therapy in a case of pernicious anæmia, with particular reference to the sternal-marrow changes. Consideration of one case obviously does not justify full assessment of the value of folic acid in the treatment of pernicious anæmia, but the observations on hæmopoiesis are of interest.

The range of hæmopoietic substances affecting the human bone-marrow has recently been extended. The hæmopoietic principle of liver, effective in very highly concentrated form in restoring the megaloblastic hæmopoiesis of uncomplicated Addisonian pernicious anæmia to normoblastic form, does not always abolish the similar megaloblastic picture which may accompany tropical or non-tropical sprue. Less highly refined and concentrated liver extracts given parenterally, or proteolysed liver or yeast extract by mouth, are often effective however, substances other than the hæmopoietic principle of liver or Castle's intrinsic factor (Castle et al. 1930) presumably being involved. The successful treatment of nutritional macrocytic anæmia with autolysed yeast extract has been attributed by Wills (1945) and Wills and Evans (1938) to a substance distinct from the extrinsic factor.

Darby and Jones (1945) and Darby et al. (1946) have reported from America that synthetic folic acid has successfully abolished or reduced megaloblastic hæmopoiesis in non-tropical sprue, with restoration of a normal blood picture. Spies (1946a) has obtained a good hæmopoietic response to folic acid, with reversal of megaloblastic hæmopoiesis, in macrocytic anæmias, including nutritional macrocytic anæmia, pellagra, uncomplicated Addisonian pernicious anæmia, macrocytic anæmia of pregnancy, and sprue.

A link is provided between the megaloblastic hyperplasia of the marrow in sprue and Addisonian pernicious anæmia, besides other megaloblastic anæmias, in that synthetic folic acid, which appears to be distinct from the hæmopoietic principle of the liver, may restore normoblastic hæmopoiesis in all these conditions. With reference to the multiple-factor hypothesis of Jacobson and SubbaRow (1937) regarding the nature of the hæmopoietic principle, folic acid also appears to be distinct from their "primary factor," which is a liver fraction active in very small amounts, especially in the presence of accessory substances. The use of folic acid in sprue by Darby and Jones (1945) and Darby et al. (1946) was the outcome of observations on the similarity between human sprue syndrome and vitamin-M deficiency in rhesus monkeys described by Day et al. (1935). This deficiency condition, accompanied by severe anæmia, leucopenia, and diarrhœa, could be prevented by giving dried brewer's yeast or liver extract, and Day et al. (1945) found *Lactobacillus casei* factor to be curative. This factor is also necessary for normal growth and hæmoglobin formation in chicks.

The *L. casei* factor had been described by Snell and Peterson (1940) as "norite eluate factor," extractable from yeast and liver, and an essential growth factor for *L. casei*. A growth factor for *Strep. lactis*, isolated by Mitchell et al. (1941) from spinach and called folic acid, was found to be widely distributed in vegetable and animal tissues. Many observers noted similarities between the properties and activities of *L. casei* factor and folic acid from various sources, and Pfiffner et al. (1943) isolated a crystalline folic-acid substance from liver with growth-promoting activity for *L. casei* and *Strep. lactis*. SubbaRow et al. (1945) finally synthesised a folic acid identical with the natural *L. casei* factor from liver.

It is this synthetic folic acid or *L. casei* factor which has been used therapeutically in man, and its structural formula, with two alternative modes of synthesis, has been published by Angier et al. (1946). The substance contains pteridyl, *p*-aminobenzoyl, and glutamic-acid groups. The extent of the natural group of substances to which synthetic folic acid belongs is not yet known. Pfiffner et al. (1945) isolated a crystalline vitamin-B_c conjugate from yeast with anti-anæmic potency for the chick but very little microbiological growth-promoting activity. They suggest that further work may reveal the relationship of several compounds—e.g., the human nutritional factor of Wills (1931) in yeast—to this crystalline factor. Darby et al. (1946) suggest the term "*vitamin-M group*" to designate substances related to folic acid and *L. casei* factor with hæmopoietic activity for primates.

Recent American work suggests that the pyrimidine base, thymine, which is identical with synthetic 5-methyl uracil (Jones 1920), may have a hæmopoietic activity similar to that of folic acid. Snell and Mitchell (1941) and Stokstad (1941) showed that thymine could be substituted for folic-acid substance as the growth factor for *L. casei*, provided substances such as adenine were present. Stokes (1944) found the bacterial cells grown with thymine to contain no folic acid; great excess of thymine is required as a substitute for folic acid, and he suggests that folic acid is a coenzyme for the synthesis of thymine or similar substances required for

the synthesis of nucleic acids. Spies (1946b) has substituted synthetic thymine for folic acid in the treatment of tropical sprue and Spies et al. (1946) of pernicious anæmia; hæmopoietic response has been obtained, but the dosage required is large (15 g. a day). Berry and Spies (1946) have recently reviewed the present status of folic acid and substances with related action.

The case to be described here has been treated by the oral administration of synthetic folic acid.

CASE-RECORD

A man, aged 63, was admitted to hospital on June 4, 1946, with six months' history of weakness, anorexia, and loss of weight. He had lost 16 lb. The skin of his face and hands had become darker; for two months there had been progressive dyspnœa on exertion.

He had been given six 1 c.cm. injections of a liver extract without improvement; the liver preparation used was six years old.

His diet before his illness had been high in carbohydrate, with deficiencies in vitamins A, B complex, and C. On admission he was placed on a hospital ward diet omitting liver, kidneys, and sweetbreads.

There was nothing relevant in past or family history.

On Examination.—Cheerful, coöperative, and emaciated. Weight 103 lb. Height 5 ft. 2 in. No orthopnœa, but dyspnœa on slight exertion. Skin of face and hands pigmented; mucosæ pale, no pigmentation. Hair grey. Temperature normal. Tongue moist, pale, with smooth surface and atrophic papillæ. Spleen just palpable. Jugular venous pressure 2 cm. above sternal angle. Resting pulse-rate 100 per min. Blood-pressure 120/45. Heart not enlarged; no added sounds. No abnormal neurological signs.

Fractional Test-meal.—Histamine-fast achlorhydria.

Neutral-red Test-meal.—No neutral red in any of the specimens of gastric juice.

Gastroscopy June 29 (Mr. Avery Jones).—Anterior wall and fundus showed gross mucosal atrophy, these changes less marked on posterior wall and not present on antrum.

Radiography.—Barium meal showed smooth mucosa, with few rugæ.

Urine.—Schlesinger's test for urobilin was strongly positive on admission, and from the fourth day of treatment onwards weakly positive.

Plasma icteric on admission. Plasma bilirubin less than 0·5 mg. per 100 c.cm. two days after start of folic-acid therapy; 1 mg. per 100 c.cm. six weeks later; less than 0·5 mg. per 100 c.cm. nine weeks from start. Direct van den Bergh consistently negative.

Hæmatological Investigations.—The peripheral blood picture before therapy is given in table I.

Blood films showed anisocytosis of the erythrocytes, with a preponderance of ovoid rather large cells and occasional very large macrocytes. There was very little anisochromasia or polychromasia. Poikilocytosis was quite frequent. The nucleated red cells present were normoblasts or intermediate erythroblasts. The neutrophil polymorphs sometimes showed excessive segmentation of the nucleus.

Sternal puncture was performed shortly after admission, and films and sections of the marrow indicated very advanced megaloblastic hyperplasia, with abnormalities in the granulocytic series leading to the formation of giant metamyelocytes and proleucocytes (table II). Hæmocytoblasts were numerous (2·2%), and the early members of red-cell and granulocytic [illegible]ies were increased. The nucleated red cells were predomi[illegible]ly members of the abnormal megaloblastic series, and all stages of hæmoglobinisation were observed. Occasio mitoses were seen, and were practically confined to t megaloblasts. There was considerable pleomorphism of t megaloblasts, and giant forms were seen with multiple nuc and moderately advanced hæmoglobinisation of the cytopla (fig. 2). The sections showed a sheet-like cellular hyperplas with obliteration of fat-spaces, and the very numero elements with basophilic cytoplasm were seen to be islets megaloblasts developing near hæmocytoblasts (fig. 1).

Therapy.—Oral treatment with folic acid was give 20 mg. was administered on each of the first two days, follow by 10 mg. daily for six days.

On the day following the start of therapy the patien general condition deteriorated, he became mentally co fused and disoriented, and showed signs of increasing co gestive cardiac failure. Jugular venous pressure 10 c above sternal angle, blood-pressure 90/50 mm. Hg. A slo drip transfusion of 250 c.cm. of packed red cells was giv carefully for six hours, followed by distinct improvement. further 250 c.cm. of packed red cells was given next da The general condition was now much improved, and t jugular venous pressure was not raised above the stern angle, blood-pressure being 110/60 mm. Hg.

The hæmatological response to therapy was good, and t peripheral blood changes are shown in fig. 7. A reticulocy response of 3·4% began on the fourth day and reached maximum of 27·6% on the sixth day. A rapid rise in t red-cell count and Hb levels was accompanied by a gradu return of the leucocytes to within normal limits.

The qualitative and quantitative changes in the sterna marrow picture are shown in table II. Early changes we apparent twenty-four hours after the start of folic-ac

TABLE II—MYELOGRAMS BEFORE, DURING, AND AFTER THERAP

Cell types	Percentage of cell types (from counts of 500 cells)

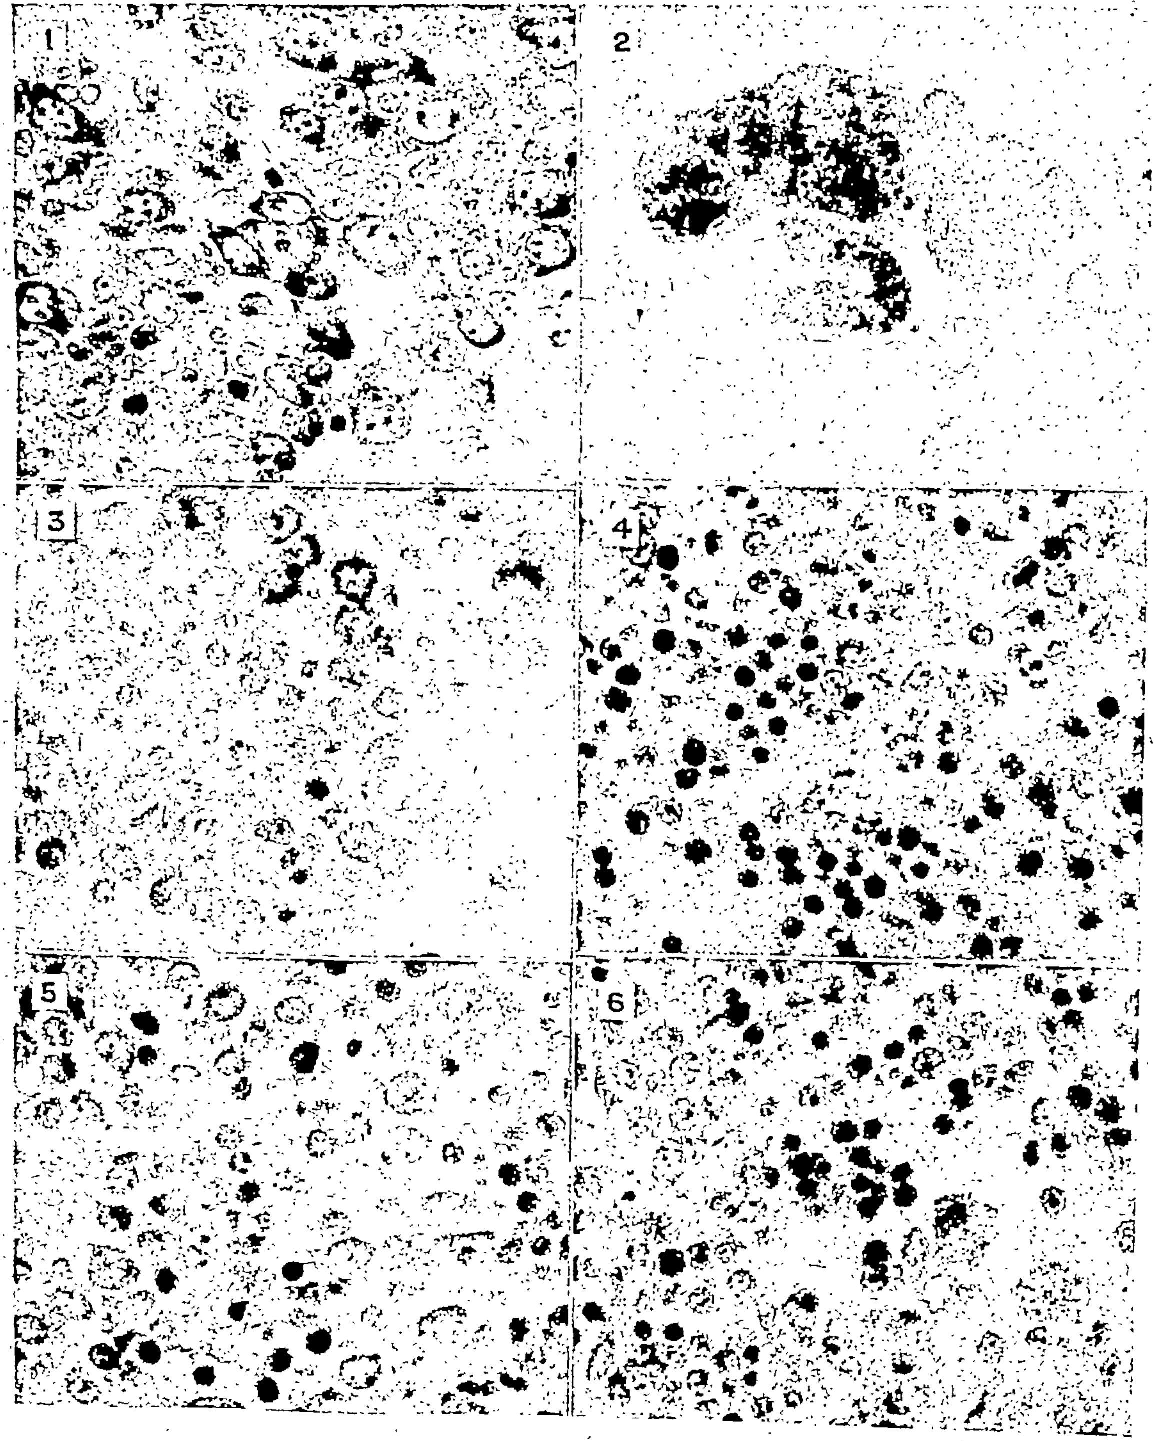
† Red-cell series.



Figs. 1, 2, 3, and 4—Sections and films of marrow from sternal punctures of the case described: fig. 1, section before folic-acid therapy, showing megaloblastic hyperplasia and increase in hæmocytoblasts; fig. 2, giant megaloblast from marrow film before therapy, showing multiple nucleus, with characteristic reticular chromatin pattern, and polychromasic cytoplasm (Jenner-Giemsa stain, × 1150); fig. 3, section twenty-four hours after start of folic-acid therapy, showing appearance similar to that in fig. 1, with aberrant granulopoiesis, and a megaloblast in mitotic division in upper right-hand corner; fig. 4, section nine days after start of folic-acid therapy, showing entirely normoblastic erythropoiesis, with darkly staining nuclei of erythroblasts and normoblasts, and occasional proerythroblasts, and normal granulopoiesis.

Figs. 5 and 6—Sections of sternal marrow from a typical case of pernicious anæmia in relapse, and following successful therapy with purified liver principle ('Anahæmin'), for comparison with figs. 1, 2, and 3: fig. 5, section before therapy (red cells 1,000,000 per c.mm., Hb 25% (Haden)), showing megaloblastic hyperplasia; fig. 6, section six days after parenteral liver therapy (reticulocytes 44%), showing actively normoblastic erythropoiesis.

All sections except fig. 2 × 580. Figs. 1, 3, and 4 fixed in Susa and stained with pyronin-methyl green. Figs. 5 and 6 fixed in methyl alcohol-formol and stained with Delafield's hæmatoxylin and azur-Giemsa (White et al. 1946).

therapy (fig. 3). The significant change was a considerable increase in mitoses in the red-cell series, seen in the earlier members of both normoblastic and megaloblastic series. Some of the mitoses were normal but others were aberrant, with formation of multipolar spindles. Amitotic division of megaloblasts was also observed. Megaloblasts were still very numerous at this time.

After ten days' treatment the megaloblastic series had completely disappeared from the marrow, and the maturation of the *granulocytes* was also entirely normal, no giant bizarre forms of the metamyelocytes and proleucocytes being seen (table II). Mitotic activity was reduced, and the biopsy specimen from the sternal marrow showed intense normoblastic erythropoiesis proceeding normally, though the cellularity of the marrow was still much greater than normal (fig. 4).

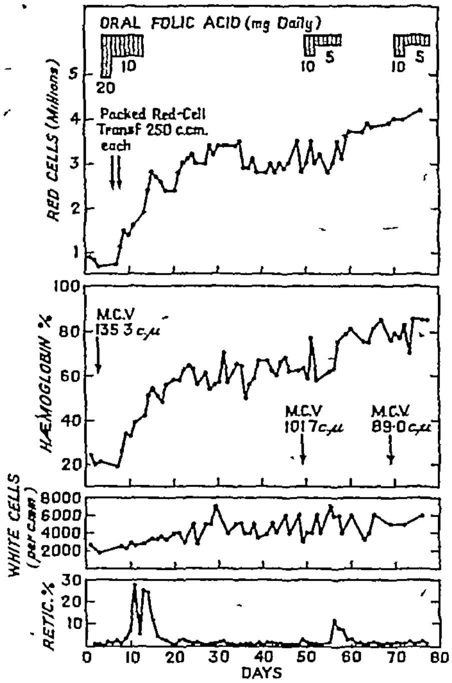


Fig. 7—Peripheral blood changes in response to folic-acid therapy.

A further sternal-marrow examination after 16 days (table II) showed a more normal cellularity, and maintenance of predominantly normoblastic erythropoiesis, but a few late megaloblasts and giant neutrophil metamyelocytes had reappeared.

The peripheral blood picture became stabilised at about 3,000,000 red cells per c.mm. and Hb 60% (Haden) (9·36 g.). The absolute values 44 days after the start of therapy were :

P.C.V. ..	28·5 c.cm. %	M.C.H. ..	34·7γγ
M.C.V. ..	101·7 c.μ	M.C.H.C. ..	34 %
		Reticulocytes	1 %

At this time the serum-bilirubin was 1·0 mg. per 100 c.cm. (*direct van den Bergh negative*), but the urinary Schlesinger test for urobilin was consistently within normal limits, being only weakly positive.

A further course of 50 mg. of oral folic acid was now given (10 mg. daily for two days, followed by 5 mg. daily for six days), leading to a reticulocyte response of 10·6% after five days. On the day following the reticulocyte peak the *patient was put on a high-protein dietary intake of 125 g.* daily.

The blood picture showed further improvement thirteen days after the second reticulocyte peak :

Red cells ..	3,900,000 per c.mm.	M.C.H. ..	30·4γγ
Hb	76 % (Haden) (11·6 g.)	M.C.H.C. ..	34·2 %
Colour-index ..	0·97	White cells ..	5000 per c.mm.
P.C.V.	34·7 c.cm. %	Reticulocytes	0·1 %
M.C.V.	89·0 c.μ.		

Films of the sternal marrow nineteen days from the start of the second course of folic acid (table II) contained some abnormally developing granulocytes and a few megaloblasts. Section of the marrow, however, showed a return to a degree of cellularity only slightly above normal. A third course of folic acid (50 mg.) was now given, in *divided dosage as before*, for eight days.

The red-cell count and Hb level continued to rise slowly, but no further reticulocyte peak developed. Six days from the start of the third course (table II) the sternal marrow showed entirely normal erythropoiesis and granulopoiesis :

Red cells ..	4,200,000 per c.mm.	White cells ..	6000 per c.mm.
Hb	85 % (Haden) (13·26 g.)	Reticulocytes	1·2 %
Colour-index ..	1·01		

Patient's condition was now very good ; *he felt* well, had an excellent appetite, and could walk without dyspnœa. The pigmentation of face and hands persisted, the tongue remained smooth, and repetition of gastroscopy (Mr. Aven Jones) revealed no change in the atrophic mucosa. It is interesting that after the folic-acid therapy he evinced a liking for fresh green vegetables for the first time.

Maintenance therapy with folic acid 20 mg. orally, twice weekly, was now instituted.

Latest blood-count, 3 months *from start of therapy* :

Red cells ..	5,000,000 per c.mm.	White cells ..	6000 per c.mm.
Hb	94 % (Haden) (14·6 g.)	Reticulocytes	1·4 %
Colour-index ..	*0·94*		

DISCUSSION

The characteristic structure of the megaloblastic bone-marrow is familiar, *particularly in pernicious* anæmia, and several descriptions have been given of the reversion to normoblastic *erythropoiesis under the* influence of the liver principle (Davidson et al. 194 Scott 1939, Wilson 1942). Interpretation of *the prese* of megaloblasts as an abnormal series never *found* in the absence of deficiency of the hæmopoietic principle has been emphasised (Israëls 1939, Jones 1943). Many observers have suggested that abnormal changes in the granulocytic series are equally as characteristic of deficiency of the hæmopoietic principle as is the coexistent megaloblastic proliferation.

La Cour (1944) considers *that abnormal* mitoses in red-cell and granulocytic series are responsible for the *formation of megaloblasts and abnormal* granulocytes in the marrow of pernicious anæmia, and that the two series show well-marked *differences in the* amounts and distribution of nucleic acids. In the marrow of pernicious anæmia and in other conditions, such as tropical sprue and macrocytic megaloblastic anæmia of pregnancy, cells with deeply basophilic cytoplasm become more numerous. These cells are hæmocytoblasts (stem cells for granulocytes and red cells), early members of the normal red-cell series, and early megaloblasts. Cytochemical tests with ribonuclease suggest that the basophilia of these cells is due to the presence of considerable amounts of ribonucleic acid (White 1946). Response of the megaloblastic marrow to hæmopoietic principle leads to rapid reversion to the normal type of maturation, with disappearance of megaloblasts and abnormal granulocytes and reduction of the hæmocytoblasts and basophilic early cell types to within normal limits.

These changes are typically seen in pernicious anæmia treated with highly purified preparations of the liver principle. Megaloblasts rapidly disappear from the marrow, mitoses are numerous in the early stages of the response, and at the time of the reticulocyte *peak* the marrow shows intense normoblastic erythropoiesis and orderly maturation of granulocytes.

The response of the megaloblastic marrow to succes folic-acid therapy appears to differ in no way from t characteristic response to purified liver principle. Report by Spies (1946a) and by Kaufmann and Schwager (1946 indicate that the essential change in *the* marrow unde therapy is a rapid reversion from megaloblastic t normoblastic erythropoiesis, with *a reticulocyte respons* and return of the red cells and leucocytes in the peri pheral blood towards normal *levels*. In the *present* cas of advanced pernicious anæmia the marrow showed complete return *to normoblastic* erythropoiesis, wit total absence of megaloblasts and abnormal granulocytes in a *sternal-marrow specimen* taken nine days afte the start of folic-acid therapy. Before treatment th predominantly *megaloblastic* erythropoiesis and accum lation of hæmocytoblasts were very striking. H metabolism also became more normal, as shown by th fall in urinary urobilin and ultimately in the reduce serum-bilirubin level.

The diagnosis of pernicious anæmia was substantiated by the changes in peripheral blood and bone-marrow, the histamine-fast achlorhydria, and atrophic gastritis.

The question arises whether the two transfusions could have provoked the hæmopoietic response. They were given twenty-four and forty-eight hours after the start of folic-acid therapy, when the patient's general condition was still precarious; it was evident that their immediate effect was good, and the cardiac failure did not increase. The well-marked reticulocyte response—3·4% initially, 27·6% at the peak—began on the fourth day of therapy, with the peak on the sixth day. It appears very unlikely that the transfusions could have been responsible so rapidly. Spies (1946a) observed incipient reticulocyte response 4–7 days after the start of therapy in five cases of pernicious anæmia, with peaks at 7–10 days, and the results in the present case strongly suggest that the folic acid was responsible. It is also unlikely that a natural remission coincided with administration of folic acid, because before the start of therapy the red-cell count and the amount of Hb actually decreased, and reticulocyte levels were low. The lack of response to liver therapy some time before folic-acid therapy was very probably due to the extract having lost potency, since it was six years old.

The initial dosage of folic acid was sufficient to effect temporarily a complete return to normal erythropoiesis and granulopoiesis in the marrow. The subsequent rise in the red-cell count and the Hb level was considerable, but continued therapy produced a second reticulocyte response, with further improvement in the peripheral blood picture. It should be noted, however, that early megaloblastic changes had reappeared before the second course of folic acid. Similar marrow findings nineteen days after the start of the second course also indicate that megaloblastic erythropoiesis and disordered granulopoiesis rapidly recur in the absence of continued administration of folic acid. These changes can be eliminated completely within a few days by readministration of folic acid, and it is evidently necessary to repeat the maintenance dosage at short intervals to sustain normal hæmopoiesis. The maintenance level has not been determined, but in the present case 20 mg. of folic acid twice weekly is to be given a trial. Further clinical trials are to be made with other cases to determine the optimal dosage.

Repeated small doses were manifestly sufficient to secure a gradual return to a normal blood picture in the present case. Davidson and Girdwood (1946) have advocated a single large initial dosage, followed by similar weekly or fortnightly maintenance doses, in pernicious anæmia.

Further knowledge is required of the possible function of folic acid as an enzyme or coenzyme before it will be possible to assess its significance in reversing megaloblastic erythropoiesis and its rôle in the normal maturation of red cells.

The position of folic acid in preventing subacute combined degeneration has not been determined yet. Signs of neurological involvement were absent at all times in the present case.

SUMMARY

The response of an advanced case of pernicious anæmia to folic acid given by mouth is described.

Therapy led to a return to normal hæmopoiesis, as shown by the changes in sternal marrow and peripheral blood.

Repeated doses of folic acid were necessary to maintain normal hæmopoiesis.

Our thanks are due to Prof. J. McMichael and Prof. J. H. Dible for their interest and assistance in this study; Dr. T. F. Macrae, who kindly made available supplies of synthetic folic acid donated by Messrs. Lederle; and numerous colleagues in the British Postgraduate Medical School for their coöperation and assistance. The photomicrographs were made by Mr. V. Willmott.

EXAMINATION OF HOME-CONTACTS OF TUBERCULOUS PERSONS

W. POINTON DICK
M.R.C.S.
PHYSICIAN I/C MASS RADIOGRAPHY UNIT, AND LATELY ASSISTANT TUBERCULOSIS OFFICER FOR MIDDLESEX

BRIAN C. THOMPSON
M.A., M.D. Camb.
TUBERCULOSIS OFFICER, OTAGO HOSPITAL BOARD, N. ZEALAND; LATELY TUBERCULOSIS OFFICER FOR MIDDLESEX

THE examination of home-contacts of tuberculous persons is one of the most important parts of the preventive work of chest clinics. It enables incipient disease to be checked and brings to light sources of infection that may be present in the home. Such examinations could well be undertaken by a mass radiography unit, and it is hoped to deal with this possibility in a further communication.

Thompson (1944) described a suggested programme for the routine examination of home-contacts and presented statistics for the years 1942–43. It is now possible to analyse the results of a close follow-up of all available home-contacts seen at the Ealing Chest Clinic during the years 1942–45. During this time 3168 persons (2025 adults and 1143 children) were examined, and 186 persons (111 adults and 75 children) were found to have significant lesions. An average of 2·5 contacts were seen for every index-case. The age-distribution of examinees and cases is shown in table I.

It will be noted that the greatest number of examinees per year of age falls into the 0–4 age-group, and that there is a steady diminution in the numbers examined as the older age-groups are approached; and that the highest percentage of cases of tuberculosis was found in the age-groups 0–4 and 15–24. These are dealt with in more detail below.

Contacts of non-pulmonary tuberculosis in whom no significant abnormality could be detected on first examination were not recalled for a further interview, the object of the investigation being essentially to find the source case. On the other hand, contacts of cases of pulmonary tuberculosis were seen at three-monthly intervals: the children for a tuberculin test and clinical examination to be followed by radiography if the skin test were positive; the adults for radiography and a clinical examination. Some persons, having attended for their first and possibly a subsequent examination, did not report again and were lost sight of. Occasionally one of these recalcitrant contacts was referred to the clinic by his doctor or a hospital and was found to have developed a significant lesion since his last attendance. In table II those persons found to have pulmonary tuberculosis are grouped according to the time of diagnosis of their disease. As would be expected, the greatest number of cases was found at first examination.

TABLE I—AGE-DISTRIBUTION

Age-group (yrs.)	0–4	5–14	15–24	25–34	35–44	45–54	55 +
Total examined	405*	738	559	450	430	356	230
No. with significant lesions	34 (8·4%)	41 (5·5%)	57 (10%)	24 (5·3%)	18 (4·2%)	6 (1·7%)	6 (2·6%)

* 255 (63%) of this group gave a positive tuberculin reaction.

An analysis of the 34 cases in the age-group 0–4 (table I) shows that with one exception they were all in contact with a sputum-positive case. Of the 34 patients 5 died (2% of the positive reactors), and all 5 had been living in infectious households. Of these children 3 were less than a year old, 1 was aged 14 months, and 1 was aged 3 years. They all died within eight weeks of diagnosis, except 1 child who died after fifteen weeks.

The great importance of examining all available contacts in the age-group 15–24 is emphasised by the fact that 1 out of every 10 persons examined in this group had a significant lesion. This is about twice the proportion found in the age-groups 25–34 and 35–44, and over four times as high as in persons aged 45 or more.

The cases of pulmonary tuberculosis among adults have been subdivided in table III according to the stage of their disease.

> The diagnostic standards of the National Tuberculosis Association of America (1940) were used, minimal lesions being defined as being without demonstrable excavation and confined to a small part of one or both lungs, the total extent of the lesions, regardless of distribution, not to exceed the equivalent volume of lung tissue which lies above the second chondrosternal junction and the spine of the fourth, or body of the fifth, thoracic vertebra on one side.

TABLE II—TIME OF DIAGNOSIS

Group	No. examined	No. with significant lesions			
		At 1st exam.	At subsequent exam.	Referred by doctor	Total
Adults ..	2025	77 (3·8%)	17	17	111 (5·5%)
Children	1143	58 (5·1%)	17	..	75 (6·6%)
Total..	3168	135 (4·3%)	34	17	186 (5·9%)

It was found that, whereas three-quarters of the cases discovered on first examination and four-fifths as the result of routine re-examination had minimal lesions, among those persons who had defaulted and were subsequently referred to the clinic the proportion of minimal lesions fell to a half. It does not follow that the defaulters fared worse than the other two groups, for there may well have been a high proportion of minimal lesions among the defaulters who did not return to the clinic.

The disposal of the 111 adults with tuberculous lesions is shown in table IV. There is a steep rise in the percentage of cases requiring treatment among those who did not remain under observation. It is also highly significant that among contacts the percentage of cases of previously undiagnosed tuberculosis requiring treatment is five times that found among the general population by mass radiography.

The Medical Research Council (1942), discuss contact examination, recommends that young adu (aged 15–30) should be radiographed at three-mont intervals and continue to be kept under observation *at least two years after contact is broken*; and that re-examination of contacts over thirty years of age m be dispensed with, if necessary through pressure of wo as being less likely to be productive of cases. The findi at the Ealing Clinic support this view. Of the 17 perso found at routine re-examination to have significa lesions only 2 were over thirty years of age. When is realised that about 60% of the adult contacts we in this older age-group, it will be seen that a very conside able saving in work could have been effected by omitti to re-examine those over thirty years of age, and th during the four years under review only 2 cases wou have been missed.

All children with significant disease were in contact wi a positive index-case, except 1 in whom contact had bee broken for thirteen months. All adults were in conta except 5 cases discovered at first or subsequent exam nation in which contact had been broken for from four t fifteen months; 5 cases discovered at first examinatio in which the index-case was negative; and 10 case discovered on reference by doctor in which contact ha been broken for fifteen months in 2 cases and for from thre to five years in 8 cases. These last patients havin previously defaulted, it was impossible to decide the exac time at which their disease had first appeared.

TABLE III—STAGE OF DISEASE IN 111 ADULTS

Stage of disease	At 1st examination	At subsequent examination	Referred by doctor
Minimal	59 (77%)	14 (82%)	8 (47%
Moderately advanced	15	3	7
Far advanced ..	3	0	2
Total	77	17	17

COMMENTS

Ideally all contacts of all cases of tuberculosis should b examined at least once. All contacts of sputum-positiv cases should be examined at three-monthly interval while contact continues and for two years after contac is broken. As a practical programme, when pressure o work is a limiting factor, all contacts should be see once, but the routine re-examination of those over thirt years of age can be omitted. Two age-groups, 0–4 an 15–24 years, require special mention as producing th highest proportion of cases. In the age-group 0–4 years 2% of those presenting a positive tuberculin reactio developed fatal tuberculosis, and all but one of those wh died were under eighteen months old. It was felt tha the only factor which could influence this result was th immediate breaking of contact with infection, and that *if the child* survived the first three months after becomin tuberculin-positive, the results were uniformly good.

TABLE IV—DISPOSAL OF 111 ADULTS

Group	At 1st exam.	At subsequent exam.	Referred by doctor	Total
Observation	45 (2·2%)	8	3	56 (2·8%)
Treatment	32 (1·6%)*	9	14	55 (2·7%)
% requiring treatment	42%	53%	82%	50%

* cf. 0·3% found by mass radiography (Dick 1945). Figures in parentheses are percentages of 2025 examinees.

The examination of all available persons in the age-group 15–24 years is of first importance in any programme of contact examination. In this group 1 in every 10 persons had a significant lesion. A constant factor in all groups was a history of present or recent contact with a positive index-case.

HYPERTENSION AND CALCIUM INTAKE

C. M. KESSON
M.D. Glasg.
CAPTAIN R.A.M.C.

A. McCUTCHEON
F.I.M.L.T.

From the Department of Materia Medica and Therapeutics, University of Glasgow, and the University Medical Clinic, Stobhill Hospital, Glasgow

THE statement has been made that a high-calcium diet is an important factor in the production of hypertension in subjects over middle age.[1] During an investigation of the ætiology and treatment of senile osteoporosis we have made observations which throw some light on the relationship between the intake of lime and hypertension.

Low Calcium Intake.—In all, 80 patients over the age of forty years were examined. Of these, 32 gave definite radiographic evidence of osteoporosis in at least three regions of the body. All were in the wards of a municipal hospital, and there is no doubt that they had been for years consuming diets with a calcium content of less than 0·5 g. a day, the amount usually accepted as the minimal intake. The percentage utilisation of lime varies considerably from subject to subject, but it seems reasonable to assume that the amount of calcium retained was not so high in the osteoporotic patients as in the others. Since all the patients came from the same social stratum, one would expect that hypertension and arteriosclerosis would be rather less prevalent in the osteoporotic group, if the retention of calcium is an important ætiological factor in hypertension.

The average blood-pressure in the osteoporotic group was 164/96, and in the other 167/96 mm. Hg. The relationship of arteriosclerosis and calcification to osteoporosis was as follows:

Arteriosclerosis found on clinical examination		*No. of patients without osteoporosis*		*No. of patients with osteoporosis*
Nil	..	13 (27%)	..	8 (25%)
Slight	..	15 (31%)	..	12 (37%)
Pronounced	..	20 (42%)	..	12 (38%)

Calcification of arteries on radiological examination		*No. of patients without osteoporosis*		*No. of patients with osteoporosis*
Nil	..	23 (48%)	..	11 (34%)
Slight	..	7 (15%)	..	12 (38%)
Pronounced	..	18 (37%)	..	9 (28%)

These results clearly indicate that there was no special association between osteoporosis and hypertension, physical phenomena of arteriosclerosis, or calcification of the vessels as demonstrated by radiography. In several patients with osteoporosis it was possible to demonstrate calcification of arm and leg vessels though the bones showed well-marked rarefaction.

High Calcium Intake.—In the course of the investigation it was found necessary to supplement the ordinary hospital diet of 19 patients with calcium salts (gluconate or phosphocarbonate) so that each patient was taking not less than 1·6 g. of calcium a day. This was maintained for periods ranging from six to fifteen months. In 9 patients the retention of calcium was determined for two weeks at the start of the investigation, and it was found that the average amount retained was 1·051 g. a day (limits 0·556 and 1·358 g.). In 2 of these patients a repeat estimation was made, in one case fourteen weeks later and in the other case eighteen weeks later. In both instances the retention of calcium still remained high (670 and 1306 mg. a day), as in the first month of the high-calcium diet. It therefore appears that throughout the investigation large amounts of calcium were retained. If a high retention of lime is an important ætiological factor in the production of hypertension, one might have expected to find some sign of hypertension in these patients. In no instance, however, was there any significant change in the systolic or diastolic pressures. In only 1 patient was there any radiological evidence of increased deposition of calcium. In this patient, a woman aged 66 years, the slight increase in the vascular shadow was not more than might be expected in a subject of that age irrespective of diet.

CONCLUSION

These findings provide no evidence that a high retention of lime prolonged over many months has any effect on the development of hypertension or on the calcification of the vessel walls.

We wish to thank Prof. Noah Morris for his interest and help, and Dr. S. Briggs, medical superintendent of Stobhill Hospital, for permission to conduct the investigation.

---

[1] Harris, I. Studies in Hypertony, Bristol, 1946.

Medical Societies

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

AT a meeting of the society in Liverpool on Oct. 4, Dr. **BRYAN WILLIAMS**, speaking on

Factors Causing Difficult Labour in Multigravidæ

said that his observations were based on women who had had at least eight normal deliveries previously; a low forceps delivery, an unaccountable stillbirth, antepartum hæmorrhage, or any other complication not directly associated with the actual birth of the child was not included as an abnormality.

In 23 cases satisfying these criteria, difficulty with subsequent labour was usually caused by either an unusually large child or some contraction of the pelvis, or both. There was convincing evidence of a tendency for babies to be larger at successive deliveries. Often the pelvis was definitely contracted; this contraction, which was acquired after the birth of the first child or first two children, was probably due to minor osteomalacic changes.

Similar changes have been noted by observers in countries, such as China, where they are very prevalent. Dr. Williams was satisfied that the lack of certain vitamins, and especially vitamin D, in the diet of many in this country causes these bony changes which eventually give rise to dystocia at some future birth.

Avoidance of Catheterisation following Vaginal Plastic Operations

Mr. A. A. **GEMMELL** said that he recommended the instillation of 1 oz. of 0·5% mercurochrome into the bladder directly after operations for prolapse, &c. A group of 63 patients was treated by this method and the results compared with those in 50 patients who had not received this instillation. Catheterisation was necessary in 9·5% of the first group, and 72% of the second. The efficacy of mercurochrome is, he considers, due to the irritant action of the solution.

Erythroblastosis Fœtalis

At a meeting in Sheffield on Nov. 1, Dr. C. C. **BOWLEY** said that erythroblastosis, which occurs only once in more than 300 labours, if untreated carries a mortality-rate of nearly 80%. Of those infants who do recover, 10% may be affected by hepatosplenomegaly or lesions of the central nervous system. Erythroblastosis fœtalis should be anticipated by routine Rh typing of the blood of every pregnant woman; and where the blood is Rh-negative, it should be examined for atypical agglutinins, at the 8th month in primigravidæ and at least once before the 8th month in multigravidæ. A previous transfusion should be considered as having the same effect as a pregnancy, and all emergency transfusions should be carried out with Rh-negative blood. When atypical agglutinins are discovered, their titre should be determined at once, and again each month until delivery; and this routine should be observed, *whether or not atypical agglutinins have been identified*, in all multiparæ with a history of children affected by erythroblastosis fœtalis. Because of the erythroblastotic infant's disposition to hæmorrhage, vitamin K should be given to the Rh-negative mother before delivery; this is effective if given as little as four hours before delivery. If given orally, it should be administered with bile salts, so as to break up the fat vehicle and to obtain maximum absorption; when given to the child, the vitamin should be dissolved in water and administered by intramuscular injection. Dr. Bowley recommended early blood-transfusion, even before the typical blood picture is seen; a Rh-negative red-cell concentrate, he concluded, should always be used, and should be given as fresh as possible.

Reviews of Books

Repertorium Pharmazeutischer Spezialpräparate

Editor: Dr. med. HERBERT LUDWIG, privatdozent an der Universität, Chefarzt am Bürgerspital, Basle; with the help of Prof. Dr. phil. F. L. FURLAN and Dr. med. E. LOELIGER. Basle: Verlagsgesellschaft Beobachter. Pp. 1308.

BEFORE the war, those who needed to find the maker and composition of Continental proprietary drugs relied chiefly on Gehes Codex. The last edition of Gehes to reach this country was published in 1937, and the last supplement in 1939; many new products, and names for them, have appeared since then. This new Swiss work, published in German, is a list of about 10,000 special pharmaceutical preparations including sera and vaccines by over 2000 different manufacturers, mostly Continental but with some British and American preparations. The information on each product, which was obtained from the manufacturer, is given under the headings: manufacturer, composition, indications, form in which issued, and dosage. In addition, pharmacological and clinical data, printed in italics and provided and paid for by the manufacturer, are given for a number of products. German and Austrian proprietaries are included since it is uncertain which of these will reappear and which will prove to have disappeared permanently. There are, besides, a therapeutic index, and a list of manufacturers and the products they issue—a helpful addition to the main text. The work is not likely to prove exceptionally useful to doctors in this country, but will appeal to all who need to know the maker and composition of proprietary drugs, particularly Continental ones.

Studies in Hypertony and the Prevention of Disease

I. HARRIS, M.D., director, Institute for Prevention of Disease, physician, Liverpool Heart Hospital; in coöperation with J. T. IRELAND, B.SC., G. V. JAMES, M.SC., EDWARD CRONIN LOWE, M.B., and C. E. VERNON, M.SC. Bristol: John Wright. Pp. 114. 12*s.* 6*d.*

CONTRIBUTIONS to our knowledge of the life-history of hypertension must be carefully but critically received. This book describes researches carried out by Dr. Harris and his collaborators at Liverpool. It includes chapters on calcium, cholesterol, the influence of fats on protein metabolism, and potassium requirement. Experiments are recorded in which calcium appeared to have raised blood-pressure in rabbits. These animals, however, were given doses which would represent an enormous amount for the human subject. Before a high-calcium diet is invoked as an important factor in the production of hypertension it seems reasonable to ask for some evidence that it raises the blood-pressure in man. None is given: instead we are treated to an outburst against the Ministry of Food, the Medical Research Council, and some scientific workers. Those who have worked in poor-law institutions will be aware that advanced arteriosclerosis can sometimes be demonstrated in patients whose intake of calcium has been very low and who show signs of calcium impoverishment. It is fairly clear that the deposition of lime in arteriosclerotic patches is a process quite different from ossification, and it will require much more evidence than Dr. Harris has so far adduced to convince us that fortification of bread with calcium is likely to lead to arteriosclerosis and hypertension.

Annual Review of Physiology

(Vol. VIII.) Editor: JAMES MURRAY LUCK, Stanford University, California. London: H. K. Lewis. Pp. 658. 30*s.*

THE editors and authors of this year's volume are to be congratulated on one of the best productions of the series. Their aim is to provide reviews of the important contributions of the preceding year or biennium, "appraise them critically, and evaluate with discrimination the present status of the subject." Many subjects of clinical interest are covered, including resistance to heat stress and cold stress, the therapeutic use of heat and cold, and the mechanism of temperature regulation; energy metabolism in relation to nutrition; physiology of the skin in relation to sweating and vascular reactions; peptic ulcer; blood-coagulation; thrombosis and hæmorrhagic disorders; clinical hæmatology; blood-groups; visceral functions of the nervous system; aviation physiology; physiological psychology; applied physiology; and sulphonamides and penicillin. Though many researches made during the war are still unpublished, some are beginning to emerge: thus, aspects of resistance to high temperature and dehydration are treated in a number of reviews, and some misconceptions and traditions relating to shock are corrected in Gregersen's article.

The World's Hunger

FRANK A. PEARSON; FLOYD A. HARPER. London: Oxford University Press. Pp. 90. 9*s.* 6*d.*

THIS brief book is—and is clearly intended to be—a corrective pill for world planners. The reader, as he takes it, should have its purpose in mind. It may purge him of a few illusions; but let him remember *that there is more, much more, to be said than the* writers admit or have even assimilated into their scientific philosophy. They are two professors of Cornell University, the one of prices and statistics, the other of marketing; and they have concentrated their attention upon consumption levels, production, and the sources of increased production. Three-quarters of the world's population live in Asia and Europe, and it cannot be assumed that the rest of the world can be so developed for food-production as to adjust this inequality. A very large proportion of the earth's surface is only partially cultivable, and only 4·3% is at present under crops—the proportion ranging from 19·9% in Europe to 1·1% in Oceania. Careful examination of soils, rainfall, climate, and so forth, leads the writers to conclude that the cultivable area cannot be very far extended—perhaps to no more than 7% of the land area of the globe. But there we may pause. The figures appear to be correct, but not enough allowance is made for man's ability to apply new methods and particularly his capacity to make better use of the soil at present under cultivation.

It is useful to be dosed with physic at times, especially since the world's population is not only unevenly distributed but still increasing; but the close of the book *is patently addressed to a transatlantic audience*, and makes one wonder how far the writers came to their conclusions before they studied their brief. Theirs is an almost shameless scientific pessimism:

> "Europe is the danger spot. It is rich in agriculture and other natural resources and has a great industrial plant. It has had a high standard of living, which has been rising. It has the second largest continental population, which has been increasing. For over a century the excess spilled over into North and South America. This honeymoon for Europe is over, however."
>
> "It seems reasonably clear that there are no large areas of new land to be brought into cultivation, that each continent will tend to manufacture an increasing proportion of the products it consumes, that immigration will continue to be restricted, and that there will be insufficient controls to prevent population from expanding."

They may be right; yet surely this is a challenge to man's innate ability to organise and overcome?

'Benadryl'

n anti-allergic and anti-spasmodic agent

Benadryl is a synthetic compound which belongs to a new and distinct pharmacological group having a specific anti-histamine action.

Extensive clinical studies have shown that Benadryl affords relief in a variety of allergic manifestations, including hayfever, urticaria, contact dermatitis and serum reactions. It is also effective in relieving the spasm of smooth muscle, such as may occur in dysmenorrhœa, etc.

Benadryl is administered orally and, in responsive conditions, it exerts a beneficial effect within a few hours. The most striking results reported have been in the control of symptoms associated with hayfever and urticaria.

Benadryl is issued in bottles of 50 capsules each containing 50 mgm., but at present supplies are limited

A booklet describing Benadryl will be sent on request

The Electronic and the Human Brain

ANOTHER war secret now disclosed is an electrical calculating machine which has been built in the United States and has been called an "electronic brain," or more accurately an Electronic Numerical Integrator and Computer—ENIAC. The principles on which this machine is constructed have been described by HARTREE.[1] Calculating machines are not new, and ENIAC does not seem to do anything qualitatively different from what simpler machines have done in the past. The use of electronic valves, howver, has enormously increased its speed and hence ts range of applicability. Built at the Moore school f engineering of the University of Pennsylvania, t operates by the counting of electrical pulses by lectronic counting circuits. If such a machine is o carry out a series of arithmetical operations it is necessary first that the required sequence should be urnished to it in such a form that it can be followed automatically and at a speed comparable with that of the individual operations, and secondly that the machine should be able to record and retain intermediate results of the calculation. Thus it requires equipment for carrying out arithmetical operations, a means of organising their sequence, and a "memory" for the numbers on which the operations are to be performed and for their results. The basic units of ENIAC are "accumulators," whose numerical portion consists of ten decade counters, one for each decimal place, a decade counter consisting of ten double-triode valves in a ring. At any one time only one valve in the ring is in the excited state, and the reception of a single pulse steps the excitation from one valve to the next. Results of the operations are put out in the form of punched cards. ENIAC can perform a multiplication in rather less than 3 milliseconds; so a computation involving altogether 10 million multiplications would take about 8½ hours.

The National Physical Laboratory is now planning a machine called ACE (Automatic Computing Engine), which will work at the speed of ENIAC, or possibly a somewhat higher speed, and will take advantage of new technical developments, permitting both a greater "memory" capacity and a higher degree of complexity in the instructions. It is intended that this machine shall be able to multiply two ten-figure numbers in 0·002 sec., and its speed and range will enable it to solve mathematical problems hitherto almost insoluble with pencil and paper. It will be able to tackle simultaneous equations with fifty or even a hundred unknowns.

ENIAC has been credited with both "memory" and "judgment." If it is to work it must retain the effects of previous excitations in such a way as to influence its response to future stimuli; but this is a property of many material systems, and the mountain might with equal truth be said to remember the glacier which grooved it. Some such electrical change occurring in the brain is doubtless the basis of true memory; but memory involves the presentation of the past to consciousness, and to apply this term to a calculating machine except by analogy is to confuse the material basis of memory with memory itself. So also with judgment. HARTREE[2] explains that in extended calculations it often happens that there are two or perhaps more alternative courses open, and it is necessary to choose between them, the choice depending on the work done up to that stage. "An electronic calculating machine can be designed and set up so that on the occurrence of a situation requiring such a selection of procedure, it first selects the appropriate criterion, if such selection is necessary, then applies it, assesses the result of applying it, and takes the action necessary to initiate the course of procedure thus indicated." This is held to imply the exercise by the machine of "a certain amount of judgment," the limiting factor being the operating instructions supplied to it. But the machine's "choice" is clearly automatic, and a calculating machine which whimsically began to exercise free will would considerably disturb the mathematicians who received the results of its operations. There is thus no basis for alarmist visions of intelligent robots making slaves of humanity. Machines, however complex, are no more than tools; and tools, as SAMUEL BUTLER pointed out, are only detachable extensions of the human body. No machine can carry out processes which have not been fathered by the human mind, though the machine's speed and efficiency may raise man's intentions to the *n*th power of beneficence or devastation.

But to compare ENIAC with the human brain is to see at once how limited, and indeed amateurish, an apparatus it is. ENIAC with its 18,000 valves consists of 40 panels 8 feet high and 2 feet wide—a total surface area of 640 square feet: the human head contains 10,000 million electrical units in the cerebral cortex alone. To apply the term brain to ENIAC is to adopt, implicitly, a conception of the working of the brain which, as Dr. F. M. R. WALSHE, F.R.S., showed in his Victor Horsley lecture delivered this week,[3] is now outmoded. Many years' study of the electrical excitation of the cerebral cortex established what may be called the popular physiological view "that the motor cortex is a close-set mosaic of points, in each of which is represented or localised a physiological unit of movement"; that is to say, the correlation between excitable cortical spot and corresponding movement is one to one, and this connection is permanent. The nervous system on this hypothesis is an immensely complicated but equally rigid ENIAC. WALSHE shows that alongside this "Newtonian" conception neurology, especially English neurology, has maintained an alternative theory, originated by HUGHLINGS JACKSON, which the most recent experimental work shows to be correct. Both discharging lesions, such as the Jacksonian fit, and destroying lesions causing hemiplegia demonstrate the existence of "leading parts" in the motor cortex, the areas for the hand, face, and foot, which are the foci of convulsions and whose movements suffer most in hemiplegia. Clinical observation also shows that it is movements and not structures which are represented in the cortex, and that the representation of movements is multiple in the sense that a given cortical focus must contain the anatomical and physiological substrata of more than a single movement. Conversely, a single movement must be represented in varying degrees of subordination throughout the motor cortex. "The 'hand area,' in brief, is merely, as it were, the macula of the field of hand movement representations." This view clearly involves a profound change in the popular idea of cortical localisation. What is localised is not a part of the body but a performance, and performances are represented not in discrete areas but in mutually overlapping fields, within each of which one locus influences another and the threshold of excitation may shift from place to place.

[3] Walshe, F. M. R. On the Contribution of Clinical Study to the Physiology of the Cerebral Motor Cortex. Edinburgh: E. & S. Livingstone. 1946.

As **WALSHE** points out, our present knowledge of cortical function is the product of the Jacksonian method—the application of conceptual thinking to the facts of observation—of which **WALSHE**'s lecture is itself a notable example. His stress on this is timely. **JOHN HUNTER**'s words to **JENNER**: "Why think? Why not try the experiment?" are often misapplied at present. None knew better than **HUNTER** that observation, though it comes first, is incomplete until it has been thought about. Today we have in medicine, if not too many observers, certainly too few thinkers. **WALSHE**'s plea for conceptual thinking is apposite also in another sense. In the world of thought outside medicine the barriers between science and philosophy are being broken down. Scientists, like **EDDINGTON**, have become philosophers because their observations compelled conceptual thinking. From the opposite direction **BERTRAND RUSSELL**[4] can say that the philosophical school of "modern analytical empiricism . . . by its incorporation of mathematics and its development of a powerful logical technique, is able, in regard to certain problems, to achieve definite answers, which have the quality of science rather than of philosophy." Science is thus becoming, once more, natural philosophy, and medicine cannot escape the challenge to thought.

Penicillin by Mouth for Gonorrhœa

THE potential importance of the oral route in penicillin therapy has been obscured by the rapidity and comparative certainty of the results with parenteral administration. When the drug is taken by mouth the proportion which can be recovered from the urine is relatively small, and it has been assumed that much of the penicillin is destroyed or inactivated by the acid of the gastric secretion. Attempts to counter this effect by applying enteric coatings to the penicillin, or by the simultaneous administration of buffer substances, have given variable results, but it has been established that the use of neutralising agents does increase the proportion of penicillin absorbed. Thus **SEAGER**[1] found that when he gave penicillin by mouth with aluminium hydroxide, magnesium trisilicate, magnesium hydroxide, trisodium citrate, or aluminium dihydroxyamino-acetate the blood-levels were considerably higher than when an equivalent dose was given in tap water. Yet these levels were still far below those attained by parente administration. As **CUTTING** and others[2] ha suggested, it seems that the gastric acid is not t only factor restricting the absorption of penicill from the gut. This has been confirmed by **McDERMO** and colleagues,[3] who estimated the urinary excreti of penicillin in six patients with complete achlorhyd when identical doses of the drug in watery soluti were given by the mouth and intramuscularly alternate days. After intramuscular injection t amount recovered from the urine varied from 36% 100% of the total dose and was in most cases mo than 60%. After oral administration the amount w only 8–32%, and thus was much the same proporti as in normal controls. In some of the patients w had received penicillin by mouth a small amount antibacterial substance, presumed to be penicilli was recovered from the stools, but this represente only a small fraction of the amount taken. It seeme probable that the remainder was destroyed by pen cillinase produced by bacteria in the intestinal trac The conclusion reached was that when penicillin given by mouth to adults, even with an effectiv antacid, the maximum amount likely to be absorbe is a third of the dose taken; and, since maximu absorption is the exception rather than the rule, a effective oral dose should be about five times as large the normally effective intramuscular dose.

This view was not supported by the findings **LITTLE** and **LUMB**,[4] who gave penicillin "stabilised with egg-white and preceded by sodium bicarbonat and found that oral administration then gave blood levels which were as high as those obtained by th parenteral route. Similarly, **BUSHBY** and **HARKNES** describe in this issue their results in the treatment o gonorrhœa with penicillin by mouth which are no inferior to the general experience with intramuscula injections. The dosage which they used in mos cases—240,000 units—is not much more than tha successfully used by **LLOYD JONES** and colleagues[5] fo intramuscular injection—namely, 150,000 units. Th latter found that the blood-level of penicillin must b maintained at 0·08 unit per ml. for nine and a hal hours to produce a high proportion of cures. **BUSHB** and **HARKNESS** obtained their best results by prolonging the dosage period to fifteen hours; but th blood-levels of penicillin in their patients were no consistently above 0·02 unit per ml., a fact whic supports their view that lower levels than thos usually thought to be essential may be effective i maintained for a longer time. They gave individua doses of 40,000 units, plus 1 g. of sodium citrate every three hours. **BOHLS** and colleagues[6] hav combined penicillin with aluminium potassium sulphate and sodium benzoate in tablets for ora medication, retarding excretion from the kidney b means of the benzoate and thus maintaining a therapeutically effective concentration of penicillin in the blood-stream for twenty-four hours. Of 36 female patients given 400,000 units of penicillin in this way, only 1 failed to respond to the treatment.

There will certainly be further developments along these lines in the treatment of gonorrhœa, for the advantages of oral medication to the patient are clear enough, and considerations of economy are fast becoming obsolete. There will be special scope for this method in the treatment of children, and HENDERSON and MCADAM[7] have shown that in infants, who have a low gastric acidity and probably a relatively sterile jejunum, penicillin is little destroyed in the gut; moreover, the inefficiency of their kidney function delays excretion.[8] The oral route will also be useful in nervous patients, and in seamen and others who have only occasional access to medical supervision. But there are dangers which these developments may render more acute, the chief being over-confidence on the part of patient and doctor. That of the patient is already manifest in the increasing proportion of those who, attending the public clinics for the treatment of gonorrhœa, cease to attend when penicillin treatment is finished. That of the doctor is shown in increasing disregard of those standards of observation and tests which should establish cure BUSHBY and HARKNESS set fairly exacting standards in their present series, but such care in assessment is by no means universal. The achievements of this " wonder drug " may obscure the incontrovertible truth that gonorrhœa remains a disease with a predilection for infectious latency. Unless this is kept in mind mistakes will be made, and mistakes may be disastrous for the individual and the public health.

Experimental Tumorigenesis

IN three lectures lately delivered at the Royal College of Surgeons Prof. ALEXANDER LIPSCHUTZ, of the University of Chile, has reviewed the observations made in his department over many years on the action of steroids in relation to " *tumorigenesis*." These observations have mostly sprung from the discovery that œstrogens injected into guineapigs cause nodules of fibrous tissue to appear in many parts of the abdomen. LIPSCHUTZ and his associates[1] have studied in detail the endocrine environment which favours or prevents the appearance of these nodules, and from data thus obtained he has elaborated hypotheses about the natural " antitumoral " defences of the body, which he believes may throw light on the problem of neoplastic growth in general, including cancer. The fibrous proliferations do not arise when œstrogens are given discontinuously—a fact which leads him to speculate on the advantages of cyclical secretion of œstrogens in the female—and they regress when the stimulus is removed. He conceives of two phases in the production of neoplastic growth: in the first, as seen in his guineapigs, there is proliferation of cells which are physiologically normal, while in the second (which may or may not follow) these cells assume the habit of autonomous, continuous, and irreversible growth. With œstrogens, he admits, the succession of these two phases is rare; " it is probable that the second phase is established by œstrogens only under certain quantitative and timing conditions," and he suggests long and continuous stimulation by very small quantities as the circumstance most likely to turn the phase of proliferation into the phase of neoplastic growth. The critical change might, he thinks, be attributed to a cellular mutation induced by continuous œstrogenic stimulation, or to a virus coming into action under the abnormal conditions such stimulation has produced.

Any close consideration of the views Professor LIPSCHUTZ has thus put before us reveals at once an important difference between his terminology and that now current here. It is clear that, though he speaks of experimental tumorigenesis and antitumoral defence, the guineapig nodules which serve him as test object are not tumours in the sense in which that word has been used of late years by British pathologists.[2] In this country the term tumour has come to be applied only to progressive new formations or neoplasms (benign or malignant) with a capacity for autonomous growth—i e., in the second of LIPSCHUTZ's two phases mentioned above. The nature of the stimulus responsible for this particular kind of cell multiplication is known only in the case of a few neoplasms in which a virus has been demonstrated—chicken tumours, Shope fibromas, Shope papillomas, kidney adenomas of frogs, and the mammary tumours of inbred strains of mice—but it is generally supposed that, whatever the causative stimulus may be, it is situated within the tumour cell. When the stimulus is not peculiar to the tumour and does not lie within the tumour cell, and when the result of withholding it is regression of the former increase in size, then the swelling is not a tumour but a simple hyperplasia. The only exception to this rule appears to be the tar wart of rabbits, which, though a true benign neoplasm, can regress and become latent. That it does not revert to its former state but merely goes into a latent state has been amply proved.[3]

Most of this orthodox pathology was recognised by LIPSCHUTZ and VARGAS[4] in their original papers describing how they produced local proliferations of fibrous-tissue cells, how they made them disappear by withholding the stimulus, and how by the combined applications of antagonistic sex hormones (alternately applied) they prevented the swellings from appearing. Though their description of these two processes as tumorigenesis and antitumorigenesis did not accord with English usage, there was reason for latitude in choice of terms, because these local hyperplasias were thought to be composed of muscle and fibrous tissue and it seemed probable that human fibromyomas would turn out to have the same origin. Human fibromyomas had been (and still are) classed as benign autonomous new growths, no extrinsic cause for them having been ascertained; and it was an advantage to place the spontaneous and experimental conditions in juxtaposition, even at the expense of exact taxonomy, until such time as both could be properly reclassified It appears now, however, that the localised fibrous hyperplasias of guineapigs do not contain any plain muscle-fibres; they are composed of fibroblasts and collagen; it has been impossible to produce them in any other species; and they are not encapsuled—the cells infiltrating slightly at the sites from which they arise. They are therefore not true neoplasms, and not analogous to uterine fibromyomas; and it seems questionable, at least, whether they have any right to retain their provisional title of tumours, even if that title is ascribed to them only by implication. This does not of course exclude the possibility that human fibromyomas may yet be found to be due to a hormonal derangement; but in that case the uterine fibroids would also lose their status in pathology as tumours and would become hormone-conditioned hyperplasias like the experimental hyperplasias of the pituitary which were once thought to be adenomas.

The discovery of these curious focal fibrous proliferations in guineapigs has been valuable in several ways. It suggested a possible cause of uterine fibroids that had not been thought of; it can be used in demonstrating what is and what is not a true tumour; and it provides in the guineapig a kind of indicator of hormone action and antagonisms. As regards these various uses, it must be admitted that we do not yet know what is the cause of uterine fibroids; and, while it is known that hyperplasias may become converted into true neoplastic tissue, there is no evidence of this happening in the guineapig lesion. As an indicator of action and reaction of the sex hormones of the guineapig these fibrous proliferations enable ingenious experiments to be done, and Professor LIPSCHUTZ in his lectures related a remarkable series. It is of course too early to predict what further knowledge this technique may reveal.

Annotations

A MORAL PROBLEM

NUREMBERG is to be followed by further trials, and among the first to answer charges of atrocious conduct will be some doctors who are said to have misused human beings in scientific experiments. The sort of crimes of which they are accused are described in a collection of narratives by medical survivors from internment camps in Czechoslovakia[1]; and the stories there told suggest a degree of degeneration which few would have thought possible in Europe. Having accepted the Nazi view that extermination of Jews and other enemies was necessary and legitimate, a number of doctors in concentration camps assisted in destroying these lives. From this it was but a step to persuade themselves that the men and women doomed to death should previously be employed as experimental material: if they were killed under controlled conditions—for example, by measured exposure to cold—data could be obtained which might later save the life of a good German soldier. Why should not science, and German arms, make use of this unusual opportunity?

From time to time during the past year or two we have been invited to publish or summarise, for the use of investigators, detailed reports of lethal experiments performed by Germans. None of these has seemed to us, on its merits, worth publicity; for the tests were generally ill conceived and ill conducted and the results no more informative than those already secured by other means. But supposing facts of real value to medicine were still to emerge from the records of the experiments—should they be published or not?

Opinion on this difficult ethical question is divided. Those who favour publication say that the crime has been committed, and that our duty both to the victims and to their surviving friends is to see that all possible advantage is gained from their sufferings, so that they shall not have suffered wholly in vain. If some good can come out of this horror, let it come. Those who would refuse publication argue, on the other hand, that the crime has been committed and that we should make ourselves accessories if we were to profit by it in any way. To do so, they believe, would make it slightly easier for someone in the future to justify another crime of the same kind; and the value of medical progress is as nothing weighed against the harm done to human values by promoting tolerance to systematic murder.

The problem was presented in simple form by a member of our profession in a novel published before the war.[2] Here a hospital doctor kills a patient so as to get information required in his researches—information which proves in fact to be of no small interest and value. After his suicide the hospital's medical committee *faces the question whether this information is to be used.* "May I remind you," says the chairman, "that our duty to our neighbour, our fellow man, comes before even our interest in science?"; and the papers are solemnly burnt. Now that the same problem may arise in real life, ought we to burn the papers? Or is this a case in which we should take the moral risk eternally involved in trying to extract good from evil?

POTASSIUM AND PARALYSIS

THE association of low serum-potassium with attacks of familial periodic paralysis has been recognised for some years, but there has been a conspicuous absence of authentic reports of paralysis associated with low serum-potassium in other conditions. An example has now been reported by Holler[1] in a diabetic girl of 18 years, admitted to hospital in coma. After the administration of 800 units of insulin in twenty-one hours ketosis was overcome, but respiratory paralysis supervened, so severe that the patient had to be put into a Drinker apparatus. Blood for serum-potassium was taken, but without waiting for the result 1·5 g. of potassium chloride was given intravenously, with great clinical improvement, the diaphragm now moving freely. The serum-potassium report was 2·5 m.Eq. per litre (9·75 mg. per 100 ml.) instead of the normal value of 5 m.Eq. After her removal from the Drinker apparatus the girl's respiratory difficulty recurred and was again relieved by potassium. On her complete recovery from all symptoms five days later her serum-potassium was found to be 5·07 m.Eq. per litre.

Two years ago Brown and colleagues[2] recorded 3 cases of chronic nephritis in which attacks of paralysis occurred spontaneously and were relieved by potassium administration, but the analytical data were somewhat scanty. Though at the time the condition did not seem so well substantiated as in the report of Holler it seems probable that a similar syndrome was involved. On the other hand, as Allott and McArdle[3] pointed out, alkalosis from pyloric stenosis is often accompanied by extremely low serum-potassium levels, without any evidence of paralysis. The syndrome of low serum-potassium with alkalosis has been reported in Cushing's syndrome by Willson and colleagues,[4] and very low serum-potassium levels are observed after testosterone treatment; in both these conditions there is no paralysis.

[4] Willson, D. M., Power, M. H., Kepler, E. J. *J. clin. Invest.* 1940, 19, 701.

Lately Darrow[5] has demonstrated that in experimental alkalosis with chloride deficiency there is a change in the muscle electrolytes, the potassium falling and being in part replaced by sodium. It seems likely that the solution of the problem why paralysis occurs in some conditions in which the serum-potassium is low and not in others must await further work on muscle electrolyte changes in these conditions. Allott and McArdle showed that the paralytic manifestations in familial periodic paralysis were not associated with a potassium diuresis but rather with a retention. So mere loss of potassium from the body is not the cause: the distribution of potassium within the body must be profoundly disturbed.

WISDOM FROM THE EGG

MICRO-ORGANISMS in general must still be studied collectively rather than as individuals, and by methods based on analogy, chance, or personal flair rather than directly on the natural host-parasite relationship. Thus the fact that most members of the genus salmonella ferment arabinose (a pentose derived from gum acacia), though interesting and useful, has little direct connexion with the problems of food-poisoning. It was by analogy that Rous and Murphy in 1911 came to use the techniques of the embryologists and showed that the fowl sarcoma could be transmitted to the developing embryo in the egg by means of a cell-free filtrate. Twenty years later Goodpasture and Woodruff succeeded in infecting the chorioallantois with the virus of fowl-pox. In the hands of Burnet and his school the technique was extended, and during the last twelve years inoculation of the developing egg with virus or rickettsia has been adapted for many purposes. The egg has advantages over the animal as an experimental subject. It is cheaper, smaller, and less liable to cross-infection; and it does not appear to harbour any natural virus infection. Inoculation may be into the embryo itself, or into the yolk-sac, the amnion, or chorioallantois, and some viruses will infect far more satisfactorily by one route than by any other. Infection of the chorioallantois often produces visible lesions which may be measured or counted, and the effects of antibodies or chemotherapy may thus be estimated quantitatively under conditions far easier to control than in an experiment involving animals.

The developing egg has already proved its value in the application of the newer knowledge of viruses and rickettsiæ to preventive medicine. Since viruses will not multiply on artificial media, one of the major difficulties in using them as prophylactic vaccines has been to concentrate sufficient volume of material in a form suitable for injection. The classical method, by the use of infected animal tissue, was used by Pasteur in anti-rabic prophylaxis, and by Nicolle and others in the preparation of anti-typhus vaccine. The fertile egg has been found to give higher yields of some viruses than can be obtained by any other method and has the added advantage that adventitious infection of all kinds can be excluded with reasonable certainty. The yellow-fever vaccine prepared in the chick embryo might well claim to have the widest social implications of any medical discovery of recent years. Whether the influenza vaccine prepared in the allantois is an effective prophylactic remains to be proved. Vaccination against smallpox with a pure strain of virus derived from culture on the chorioallantois is feasible, effective, and free from the risks of secondary infection. Virus from the developing egg has been shown to be a more satisfactory reagent for the Frei test in the diagnosis of lymphogranuloma inguinale than sterilised pus or mouse-brain suspension. Inoculation of the yolk-sac has been used by Cox in the preparation of rickettsial vaccines against epidemic and murine typhus and Rocky Mountain spotted fever.

The growth of viruses and rickettsiæ on the developing egg presents no great technical difficulties, and the monograph by Beveridge and Burnet,[1] just published, describes those practical devices without which the investigator in any new field must flounder until luck and perseverance teach him foolproof methods. The monograph reviews the history and present status of the technique in all its aspects, but says little or nothing of the future possibilities, though these must be far from exhausted—for example, in the experimental chemotherapy of virus infections, which is still in its infancy; and, since bacteria can be grown on the egg at least as well as on artificial media, in the rapid diagnosis of bacterial infections. This monograph originates from Australia, where much of the pioneer work on this subject has been done; it will make the bacteriologist in Britain view his empty egg-cup with increased regret.

ENDS AND BEGINNINGS IN INTERNATIONAL HEALTH

CONTRASTS between the old and new in international public health were apparent at what may be the last meeting of the Office International d'Hygiène Publique in Paris on Oct. 23, followed by the second session of the Interim Commission of the World Health Organisation at Geneva on Nov. 4.

The Permanent Committee of the Paris Office occupied itself chiefly with good-tempered arrangements for its own funeral. The director-general, Dr. Robert Pierret, offered his resignation to facilitate the transfer, and it was agreed that the work of epidemiological reporting, as well as some of the staff, should be transferred to the Interim Commission by the end of the year. When the protocol enters into force[1]—possibly about next March—formal transfer of the funds and other assets will take place. It seems likely that the assets of the Office will not exceed the ultimate liabilities for pensions, compensation, and the like, unless member countries pay up their arrears of contributions. True to a forty-year-old tradition the president of the Permanent Committee, Dr. M. T. Morgan, managed to obtain agreement even on the most controversial subjects, and no voting was necessary. Naturally the technical discussions were thrust somewhat into the background, but interesting papers were submitted, notably by Dr. P. G. Stock, Dr. Vollenweider, and Dr. G. Stuart on the "immune reaction" following anti-smallpox vaccination, by Dr. van den Berg on postvaccinal encephalitis, and by others on B.C.G., plague, and typhus.

Of the 18 members of the World Health Organisation's Interim Commission, 17 met in Geneva—only Dr. Medved of the Ukraine being unavoidably absent. Although a smaller body than the Permanent Committee of the Paris Office, it is still too large for the expeditious conduct of its business, and the meeting, scheduled to last for seven days, went on for ten. This was partly due to inevitable lack of experience of many of the delegates in this type of work, to translation delays, and to the birth-pangs of a new organisation, but an important cause was the natural desire of members to press for work to be undertaken or committees to be set up on the specialty or disease in which they happened to be personally interested. Fortunately, as Dr. Melville Mackenzie pointed out, the Interim Commission is precluded from dealing in its short life with anything except "urgent" health problems: but, even so, the secretariat has been given "an almost impossible burden" in addition to its statutory obligations such as those concerning the international sanitary conventions, the nomenclature of diseases and causes of death, the they are not encapsuled—the cells infiltrating slightly at the sites from which they arise. They are therefore not true neoplasms, and not analogous to uterine fibromyomas; and it seems questionable, at least, whether they have any right to retain their provisional title of tumours, even if that title is ascribed to them only by implication. This does not of course exclude the possibility that human fibromyomas may yet be found to be due to a hormonal derangement; but in that case the uterine fibroids would also lose their status in pathology as tumours and would become hormone-conditioned hyperplasias like the experimental hyperplasias of the pituitary which were once thought to be adenomas.

The discovery of these curious focal fibrous proliferations in guineapigs has been valuable in several ways. It suggested a possible cause of uterine fibroids that had not been thought of; it can be used in demonstrating what is and what is not a true tumour; and it provides in the guineapig a kind of indicator of hormone action and antagonisms. As regards these various uses, it must be admitted that we do not yet know what is the cause of uterine fibroids; and, while it is known that hyperplasias may become converted into true neoplastic tissue, there is no evidence of this happening in the guineapig lesion. As an indicator of action and reaction of the sex hormones of the guineapig these fibrous proliferations enable ingenious experiments to be done, and Professor LIPSCHUTZ in his lectures related a remarkable series. It is of course too early to predict what further knowledge this technique may reveal.

Annotations

A MORAL PROBLEM

NUREMBERG is to be followed by further trials, and among the first to answer charges of atrocious conduct will be some doctors who are said to have misused human beings in scientific experiments. The sort of crimes of which they are accused are described in a collection of narratives by medical survivors from internment camps in Czechoslovakia[1]; and the stories there told suggest a degree of degeneration which few would have thought possible in Europe. Having accepted the Nazi view that extermination of Jews and other enemies was necessary and legitimate, a number of doctors in concentration camps assisted in destroying these lives. From this it was but a step to persuade themselves that the men and women doomed to death should previously be employed as experimental material: if they were killed under controlled conditions—for example, by measured exposure to cold—data could be obtained which might later save the life of a good German soldier. Why should not science, and German arms, make use of this unusual opportunity?

From time to time during the past year or two we have been invited to publish or summarise, for the use of investigators, detailed reports of lethal experiments performed by Germans. None of these has seemed to us, on its merits, worth publicity; for the tests were generally ill conceived and ill conducted and the results no more informative than those already secured by other means. But supposing facts of real value to medicine were still to emerge from the records of the experiments—should they be published or not?

Opinion on this difficult ethical question is divided. Those who favour publication say that the crime has been committed, and that our duty both to the victims and to their surviving friends is to see that all possible advantage is gained from their sufferings, so that they shall not have suffered wholly in vain. If some good can come out of this horror, let it come. Those who would refuse publication argue, on the other hand, that the crime has been committed and that we should make ourselves accessories if we were to profit by it in any way. To do so, they believe, would make it slightly easier for someone in the future to justify another crime of the same kind; and the value of medical progress is as nothing weighed against the harm done to human values by promoting tolerance to systematic murder.

The problem was presented in simple form by a member of our profession in a novel published before the war.[2] Here a hospital doctor kills a patient so as to get information required in his researches—information which proves in fact to be of no small interest and value. After his suicide the hospital's medical committee faces the question whether this information is to be used. "May I remind you," says the chairman, "that our duty to our neighbour, our fellow man, comes before even our interest in science?"; and the papers are solemnly burnt. Now that the same problem may arise in real life, ought we to burn the papers? Or is this a case in which we should take the moral risk eternally involved in trying to extract good from evil?

POTASSIUM AND PARALYSIS

THE association of low serum-potassium with attacks of familial periodic paralysis has been recognised for some years, but there has been a conspicuous absence of authentic reports of paralysis associated with low serum-potassium in other conditions. An example has now been reported by Holler[1] in a diabetic girl of 18 years, admitted to hospital in coma. After the administration of 800 units of insulin in twenty-one hours ketosis was overcome, but respiratory paralysis supervened, so severe that the patient had to be put into a Drinker apparatus. Blood for serum-potassium was taken, but without waiting for the result 1·5 g. of potassium chloride was given intravenously, with great clinical improvement, the diaphragm now moving freely. The serum-potassium report was 2·5 m.Eq. per litre (9·75 mg. per 100 ml.) instead of the normal value of 5 m.Eq. After her removal from the Drinker apparatus the girl's respiratory difficulty recurred and was again relieved by potassium. On her complete recovery from all symptoms five day later her serum-potassium was found to be 5·07 m.E per litre.

Two years ago Brown and colleagues[2] recorded cases of chronic nephritis in which attacks of paralys occurred spontaneously and were relieved by potassiu administration, but the analytical data were somewh scanty. Though at the time the condition did not see so well substantiated as in the report of Holler it seem probable that a similar syndrome was involved. O the other hand, as Allott and McArdle[3] pointed out alkalosis from pyloric stenosis is often accompanied b extremely low serum-potassium levels, without an evidence of paralysis. The syndrome of low serum potassium with alkalosis has been reported in Cushing' syndrome by Willson and colleagues,[4] and very lo serum-potassium levels are observed after testosteron treatment; in both these conditions there is no paralysis

CARE OF THE ELDERLY *

Lord AMULREE
M.D. Camb., F.R.C.P.

DURING the past few years the care of the elderly has assumed a particular importance in England, and it has been realised that their welfare propounds a problem that it will be difficult to solve. One hesitates to use these rather cold and impersonal words to describe what is essentially a human responsibility, and I should like to emphasise from the start that this is a matter from which the hand of the bureaucrat should be kept as far as is possible.

How to provide adequate living conditions for the elderly, and how to give them their proper place as essential members of the community, is likely to be the great social question of the future.

THE AGEING POPULATION

In the United Kingdom during the last forty years the average expectation of life has increased by 17 years for men, to an age of 61, and by 20 years for women, to an age of 67. In 1901 there were about 2,400,000 persons (1,100,000 men and 1,300,000 women) aged 60 or over, but by 1944 the number had risen to 6,300,000 (2,700,000 men and 3,600,000 women).

This change in the constitution of the population is partly attributable to differences in the birth-rate, but partly also to prevention of many of the great killing diseases, with healthier living conditions generally and a higher standard of living among poorer people. The successful prevention of disease, especially in the young and middle-aged, makes it likely that in the next fifty years patients admitted to acute hospitals will be drawn more and more from the higher age-groups.

In a short time—if indeed it has not already happened—the real workers, between 18 and 60 years of age, will form only 40% of the population. Economically, it would not be satisfactory for 40% to carry the other 60% as drones, and from this purely practical point of view, if from no other, old people must be preserved as working members of the community for as long as is possible. This does not, of course, mean that they should be encouraged or expected to undertake heavy manual work; but that they should do light work and be employed in other ways where their wisdom and experience can be used to the full seems to be as natural as it is desirable. That it can be done was shown during the late war, when many men, and women, continued to work for some years after they would normally have retired—and with little damage, but rather improvement, to their health.

WHERE TO LIVE?

Compared with former, and perhaps happier, times, many more old people are faced with the problem of how to carry on their daily routine. Increased taxation, smaller houses, and lack of domestic help—a factor of great importance—are compelling many of the elderly to seek assistance even though they are by no means destitute. And this loneliness is one of the terrible aspects of old age. In 1944 there were over half a million pensioners on the supplementary pensions list who were living alone (including of course those in hostels or boarding-houses), and 85,000 of these were over 80 years of age.

What are the alternatives now open to those who, through no fault of their own, find that they are unable to deal with their own housekeeping, or indeed to look after themselves adequately?

In the first place there are the public-assistance institutions. No-one can say that most of these are in any way satisfactory; their buildings are old and hideously decorated, with no human comforts, run under a lay administration with any number of encumbering and intimidating rules. There is, however, one valuable aspect of this system which must not be lost sight of in any impulse to sweep away the monstrous relics of the past. Those who are destitute, old, and ill can find a lodging in these institutions—a bed, food, and devoted nursing when it is needed. Granted that a lot, including the medical care, was bad; the system nevertheless has certain merits which must not be overlooked.

Then there are hostels and the like, mostly run by voluntary bodies, but a few by enlightened local authorities. Some of these are good, and some indifferent; but whatever their virtues or their faults their number is small, and they do no more than touch the fringe of the problem.

SOME REQUIREMENTS

One great difficulty has been that no-one has ever laid down the criteria necessary to make a satisfactory home for the elderly. For these are minimum requirements which apply no matter what type of building is selected.

It is probably a mistake to collect old people together into self-contained communities, unless these are situated in the middle of towns and unless there is complete freedom for the old to leave the home whenever they like and to receive visitors at any reasonable hour. In general the old enjoy the society of the young, and the young can learn much from contact with their elders. Plans for new blocks of flats or for housing estates do, from time to time, contain provision for a certain number of flats or houses specially made for the elderly. Rooms should if possible be on the ground floor; but, if this cannot be arranged, nothing higher than the first floor should be used and an easy staircase provided. The staircase should be well lighted, should have a handrail on each side, and should not be a spiral; if a turn has to be made this should be done by means of a half landing. In any building inhabited by the elderly, care must be taken that the stair-carpet is in good condition and not loose. Some 10% of fatal domestic accidents to people over the age of 60 can be traced to an accident on the stairs.

If possible floors should be made of some non-slip material. A hand-chain over the bath, which may be of the sitz type, is of advantage. Fires, whether open, electric, or gas, should be adequately protected—over 5% of fatal domestic accidents to people over 60 are due to burns from improperly protected fires. The house, or flat, should not be too large; a living-room with a curtained bed recess, a bathroom and kitchen, are usually all that an elderly person wishes to look after. A good example of such flats is to be seen at the Glasgow corporation's Crookston institution. The bed recess is important during the winter, because it enables the occupant to sleep in the same atmosphere as that in which he has spent the day, thus avoiding sudden chills. An internal w.c. should always be provided, and the coal store should open into the house.

When hostels are proposed, care must be taken that each person has the possibility of as much privacy as he desires. While it is true that the old feel lonely, they do not always want to pass all their time in full public view. Single rooms are of course the ideal; but where this is impossible, small wards, or rooms, of not more than six beds (preferably less), should be provided. By the skilful use of screens and curtains the beds can usually be arranged so that inmates can retire into their own world from time to time. It is a great advantage for the occupants of hostels to bring their own furniture and belongings. Personal possessions acquire an increased value with old age, and their continued presence goes

* A paper read at the opening session of the Anglo-Swiss Medical Conference at Basle, 1946.

control of narcotics, and biological standardisation. *Yet tuberculosis, the outstanding problem in world* health at the present time, was hardly mentioned. Underlying this problem is an important point of principle, since it involves the question how far the members of the Interim Commission, who are nominated by governments in their personal capacity, are responsible to, and should receive instructions from, their own governments. It was evident that some members consider themselves primarily as representatives of their countries, while others clearly spoke for themselves alone; and although the point was raised by Dr. Mani (India) it was not specifically discussed. The narrower functions of the Paris Office make possible a dichotomy, delegates speaking under instructions in administrative matters concerning the conventions and personally on scientific matters; but in bodies such as the old Health Committee of the League of Nations, and the Interim Commission, which have wider powers of spending money on the initiation of work, such a distinction is probably impracticable. It may be that a mixture of responsible and irresponsible members—of civil servants and "rash, inconsiderate, fiery voluntaries"—is not only inevitable but desirable; but more will certainly be heard of the question.

Among the important decisions taken was one to accept UNRRA's generous offer of 1½ million dollars—half as much again as the commission's budget for 1947. It will be used in the first place to continue certain aspects of UNRRA's health work, including medical fellowships, the programmes in China and Ethiopia, and the control of tuberculosis and malaria: meanwhile governments of countries receiving aid from UNRRA will be asked to review their needs, so that the programme for spending the balance of the money can be revised. This should bring to the Interim Commission and the World Health Organisation additional strength by adding practical field work to their more academic responsibilities, as well as partially salving many consciences dismayed by the premature ending of UNRRA's activities. But how far governments will wish to accept expert advice unaccompanied by more tangible aid remains to be seen.

A stubborn debate took place on whether the headquarters of the Interim Commission should remain in New York or be transferred to Geneva, with a liaison office in the United States. An eloquent plea for Geneva by the executive secretary, Dr. B. Chisholm, on grounds of practicability and cost, was supported by the chairman, Dr. A. Stampar, and (as regards epidemic notification and the transfer of UNRRA work) by Dr. N. M. Goodman, the observer for UNRRA. But the commission felt that the more intangible considerations in favour of a New York headquarters were of paramount importance, and a vote on a compromise motion to retain headquarters there but establish a regional office in Geneva to deal with epidemiological reporting and the UNRRA field work in Europe revealed only two dissentients, Dr. Cavaillon and Dr. Krotkov, the members from France and the U.S.S.R. The next meeting of the Interim Commission is scheduled for March 31 in Geneva, and meanwhile the secretariat will have to increase its staff to deal with its new responsibilities.

DROWSINESS FROM BENADRYL

THE drug 'Benadryl' (β-dimethylaminoethyl benzhydryl ether hydrochloride) has anti-allergic properties and also an anti-histamine action which enables it to relieve spasm of smooth muscle.[1] It is given by mouth in capsules of 50 mg., the average adult dose being one to four capsules daily. It has been used with great success in urticaria, angioneurotic œdema, erythema multiforme, and hay-fever; and Willcox[2] has shown that the urticaria which occasionally follows penicillin therapy also responds well. It is not, however, without toxic effects, the most prominent being drowsiness, and Slater and Francis[3] describe a case in which an accident resulted from this symptom. A hay-fever patient took a 50 mg. capsule of benadryl at 7 A.M. and complained of feeling drowsy on starting work at 8 A.M. An hour later, while driving an electric platform cargo truck, he lost control and jumped off the truck. He was not hurt, but the truck ran off the platform and was wrecked.

More than half the patients taking benadryl notice slight drowsiness, and a few sleep for anything up to 18 hours at night, though this effect usually wears off in a day or two. When drowsiness is severe the dose may be reduced to 10–20 mg. A possible alternative would be to give amphetamine ('Benzedrine') in doses of 5 or 10 mg at the same time. In the treatment of epilepsy it has been found that large doses of phenobarbitone (e.g., gr. 3 daily), which alone produce intolerable drowsiness, will still have the same effect on the fits if given in conjunction with amphetamine, though their hypnotic action is much reduced.

WELFARE OF THE DEAF

DEAFNESS in early childhood is not always easy to detect, and it is often difficult to decide whether a child's failure to develop normal speech is due to deafness or to mental retardation. Ascertainment at an early age is extremely important because the deaf child can acquire speech and language only by expert teaching, and until he has done so no other education is practicable. Under the Education Act, 1944, the parent of a deaf child can ask the local education authority to provide special education for his child from the age of two years, and an increasing number of parents are applying for these facilities. Unfortunately, however, the schools for the deaf are still suffering from war-time interruptions. Several of the largest of them, which were evacuated from dangerous areas, are only just beginning to settle down in their original premises. Most of the schools are residential and have had great difficulties in securing adequate domestic staff. The total number of trained teachers of the deaf is comparatively small so that the claims of the Armed Forces inevitably hit some schools hard. The training of teachers for so highly skilled a profession takes time, and there is still a shortage of suitable premises. The development of group hearing-aids for teaching purposes, which had made a good start before the war, was held up by difficulties of supply and maintenance. The solution of these problems is not a matter of weeks or even of months, but, in reply to an eloquent appeal by Mr. Edward Evans in the House of Commons on Nov. 20, reported on another page, Mr. Key, parliamentary secretary to the Ministry of Health, assured the House that the Minister of Education was urging local education authorities to make more provision for deaf children, and that conferences were being held to consider the erection of new schools and the extension of existing ones.

Three committees of the Medical Research Council are at work on different aspects of deafness. Most has been heard of the Electro-Acoustics Committee, which is concerned with the design of a hearing-aid which will be provided and maintained free of cost under the National Health Service. The two other committees are studying medical and surgical questions and the educational aspects. The findings of these committees will no doubt be valuable, but the various problems of deafness need for their solution the coöperation of doctors, physicists, educationists, and social workers. Doctors can help by ensuring that every child who develops otitis media receives early and efficient treatment, and by encouraging the parents of deaf children to seek the aid of the local education authority as soon as possible.

medicine in Baltimore. In addition, the delegation met representatives of the council on medical education and hospitals of the American Medical Association in Chicago, and of the National Board of Medical Examiners in Philadelphia.

"From all these bodies the delegates obtained valuable information as to the requirements for medical practice, the content and layout of the medical curriculum, and the views of those who would amend the existing regulations."

A preliminary report on the visit would be presented during the session, when the council would have to consider the draft recommendations in the light of observations made on them by licensing bodies and medical schools; but since replies had not been received from a number of bodies and schools it would probably be necessary to have an additional session in February for adoption of the recommendations in their final form.

At their May meeting the council approved the draft of a short Medical Bill restricted in its scope to matters which in their opinion urgently required legislation. Copies of the draft and of an explanatory memorandum were transmitted to the Minister of Health and to the Lord President of the Council on Sept. 21, with a submission that the Bill should be settled by the Government draftsman with a view to its introduction, as settled, into Parliament at the first opportunity.

YES OR NO?

FURTHER COMMENTS

LAST week we published extracts from published comments on the British Medical Association's plebiscite. The following is a further selection:

Sir ALFRED WEBB-JOHNSON (*president of the Royal College of Surgeons of England*):

I hope that all practitioners will give this question most serious consideration. I trust that they will not lightly make it difficult for the responsible leaders of the profession to enter into negotiations in which the Minister is now at liberty to take part.

It must be borne in mind that a vote in favour of discussions with the Minister does not register approval of the Act in every detail. A vote in favour of discussions does not commit any practitioner to accepting service under the Act.

There are parts of the Act which, in the judgment of the majority of the profession, will not give the public the best service. But the Act probably pleases no-one entirely. There are obvious dangers to be guarded against.

Discussions will, however, provide opportunities for negotiation on many points which still need clarification in spite of the debates in Parliament. They will also provide opportunities for helping to plan most of the machinery of the service, and to mould much of the policy which remains to be settled by regulations.

Dr. GUY DAIN (*chairman of council, B.M.A.*):

Mr. Souttar accuses the B.M.A.'s leaders of "blind opposition" to the Health Act, when in fact they are adopting the most democratic step open to them—that of taking the opinion of the whole profession, an opinion that through the plebiscite will determine all future action. He says that the medical profession will never refuse to serve the nation. Of course it will not. But it has the right to determine by its own faith and conscience whether the Act can in fact be made to work in the best interests of the people. (*Times*, Nov. 20.)

Dr. CHARLES HILL (*secretary, B.M.A.*):

Let me make it clear, with all the emphasis I can, that whatever the result of this plebiscite the medical profession's services to the sick and the suffering will not be diminished in the smallest degree. No patient in this country is going to have one bottle less medicine, one minute less of care and attention, on account of the doctors' little disagreements with the present Minister of Health. . . .

Nor, again, is it either true or fair to pretend that this plebiscite is (in some unexplained fashion) disloyal or "seditious," to argue that the B.M.A. is "challenging the authority of Parliament" by organising it. We are not yet faced in this country, thank God, with the alternative of signing on the dotted line or going to prison, the choice (let us say) between "Bevan or Belsen."

All doctors are expressly left free by the Act itself to choose whether to come into the new Health Service or not. . . .

No, the "supremacy of Parliament" is being insidiously and corrosively tampered with by people other than the B.M.A. One of the many reasons why doctors dislike this Act is that it is the worst sample yet seen in England of delegated legislation, of the fatal temptation to leave the making of law to the bureaucrat. . . .

This ill-judged scheme hurriedly rushed through Parliament is not a proper Statute at all. It is not even an "Enabling Act." It is just a Sahara of blank spaces in which a temporary political office-holder may scrawl anything. That is the ugly fact behind the much-advertised vision of a "free health service for everybody."

That is the issue this plebiscite will test. Naturally, and rightly, doctors are being told what their professional leaders think of the Act as it now stands. But the illusion, sedulously fostered by opponents, that the average doctor would be quite willing to work with Mr. Bevan if it were not for the intrigues of some mysterious clique or "faction" at the B.M.A has no foundation in fact. (*Evening Standard*, Nov. 20.)

Sir WILLIAM GOODENOUGH and Sir JOHN STOPFORD, F.R.C.P., F.R.S.:

It is not for us to interfere in any way in the internal affairs of the medical profession, we are concerned not with medical practice but with university and hospital administration. Nevertheless, because of these concerns, the future of the health service is a matter of vital importance to us and to the patients and students whom we serve, and this future depends upon the attitude towards the service of the doctors and others by whom it will be operated. . . .

It seems to us that if the profession decide now not to take part in any discussion with the Government, they will be forfeiting their right to share in the shaping of the new service and will be deciding in advance to reject the scheme which has been approved by Parliament before they have any knowledge of what that scheme in fact will be. We earnestly hope that our medical colleagues will not take hastily so rash a decision but will join with the Government and with all others concerned to discuss how best the Act can be translated into an effective health service. (*Times*, Nov. 25.)

BRITISH AND AUSTRALIAN MEDICAL SERVICES COMPARED

FROM OUR AUSTRALIAN CORRESPONDENT

"THE panel system in Britain has broken down so completely that the Government has been forced to bring out a new scheme," said Dr. A. W. Chambers, an Australian doctor who has just returned after nine years in England and Scotland. "The standard of the medical profession in Britain today is high, except for general practitioners, who have deteriorated considerably because they have not the time to bring themselves up to date," he is reported as saying.

"Patients in public hospitals in Britain paid according to their means. There was nothing comparable to the six shillings a day subsidy for hospital patients paid by the Australian Government.

"Britain was far behind Australia in maternal care. Many children were still delivered in the mother's home with the aid of a certified midwife. Every British mother did not receive a maternal benefit as in Australia.

"Only the working girl, a contributor to the National Insurance Scheme, received a grant of less than £5 for her confinement if a child was born to her within a certain time of her leaving work."

In Australia, since 1943, a mother has received £15, £16, or £17 10s. according to whether there are none, one or two, or three or more other children under 14 in the family.

AUSTRALIA'S NATIONAL HEALTH SCHEME

It may be of interest to British readers to recall that Australia has a National Health Scheme which passed both houses of parliament in 1938 but has never been put into operation.[1] The scheme was compulsory, but did not cover everyone. It was limited to employees, other than public servants, having an income of less than £7 per week. In 1939 the scheme would have applied to only a quarter of the population of Australia.

a long way towards relieving the sorrow natural upon giving up a home. There are some old people who prefer to share a bedroom; they feel lonely and frightened at night and enjoy the feeling of someone in the room.

LESSONS FROM CHELSEA AND FRANCE

One of the best provisions made for the elderly in Great Britain is the Royal Hospital, Chelsea, founded by King Charles II for Army pensioners.

Here about 600 men, ex-Regulars of good conduct, are housed in large wards. But each pensioner has a cubicle of his own, containing his bed, chest-of-drawers and chair, into which he can retire and shut the door. The ward is large, with plenty of space, light, and air. There is a large open coal fire, with arm-chairs, while at one end is a small stove where any of the pensioners can cook a sausage, or the like, if he so wishes. This is of course in addition to his regular meals. Each pensioner is given a monetary allowance for beer and tobacco; and he can leave the building more or less as he likes. He also has at least three suits—a scarlet one for Sundays and feast-days, a blue one for ordinary days, and a fatigue dress for wearing in the hospital.

The beer-and-tobacco allowance, together with a wardrobe of reasonable size, go a long way towards making the lives of these men appear as normal as possible. Too often an atmosphere of quite unnecessary restriction surrounds such institutions; any attempt to indulge in mild human weaknesses or pleasures is regarded as improper, and the unfortunate inmate is treated as if his poverty and helplessness were a crime. It is a gloomy commentary on the progress of mankind that the best institution of this kind in England dates back 350 years.

Attached to this hospital is an infirmary where pensioners can go when they are sick of mild or minor diseases (for anything serious they are sent to a military hospital) or where they can be permanent inmates when they become feeble. During the war the infirmary was removed to a large house in the country, where the pensioners enjoyed the benefits of a beautiful garden and park, as well as immunity from bombs. The old gentlemen were, however, completely miserable, and only longed to return to London. The house was about two miles from a small country town—too far for them to walk, or for their friends to pay them visits. They missed the noises of the town, the sight of the traffic, and the feeling of being a member of a vast community. This experience has been instructive, for it is often suggested that large country houses might be converted into homes for the elderly. We must recognise that in general old people need to be kept in touch with the community, where their friends and relatives can see them with ease and where they still have the surroundings they have always known: otherwise there will be no contentment in their old age. Their life is contracting, and what is still left is doubly precious on that account.

In France great attention has been paid to the care of the aged for many years. The Assistance Publique, the central authority which controls all but a small number of the hospitals, is responsible for providing accommodation and care for old people. Under this authority homes, which may be roughly divided into three categories, are available—those who can afford to pay a sum equivalent to approximately £1 a week at the present rate of exchange can obtain a large bed-sitting-room furnished by themselves in one of the many *maisons de retraite*. Here medical attention, under the hospital authority, is available, food is served in a common dining-room, and there are practically no rules governing the institution. For those who cannot afford this sum, smaller rooms, *petits ménages*, are available in large institutions, which are equally free from tiresome restrictions. And even the paupers, housed in large dormitories in somewhat old-fashioned institutions, or hospices, are allowed a degree of freedom which compares favourably with tha enjoyed by inmates of our public-assistance institution But, from the medical point of view, the most importan fact is that the healthy aged are cared for by the sam authority as the sick, and there is, therefore, no administrative barrier fixed between these two inseparable type of old people.

Any arrangements made for the care of the elder in hostels, homes or institutions must include a clo link with a hospital. Old people develop mild disease notably respiratory or cardiovascular, which prom care will often cure in a short time, whereas neglect m lead to catastrophe. The aged do not react to infecti as vigorously as the young, and apparently trivi symptoms may mask a serious condition. It is tr that the old frequently object strongly to removal hospital, because they have a secret fear that they w never leave. An efficient hospital service can in tin overcome that fear; when they see their friends returnin from hospital, improved in health, if not cured entirel they no longer regard their own transfer to the hospit as the first step to the tomb.

At present elderly persons who become ill are ofte taken away from home to some institution, where the are put in a ward for the chronic sick. Here they l until they die—receiving no proper medical investigatio or treatment—and are made unnecessarily bed-fas Then life becomes miserable and cramped, and the occupy valuable beds which are required for oth purposes.

AN UNPAID DEBT

What I have been saying is obvious once it comes t the mind.

We have already made great strides with the improv ment of conditions for infants and young children, an this has paid handsomely. Let us now turn our attentio to the old, who, having worked all their lives, can pay n dividend: in fact it is we who owe them much. Thei plight is desperate.

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

OPENING the 169th session on Tuesday last Sir HERBER EASON, the president, spoke with deep regret of th death of Sir Kaye Le Fleming—a direct representativ for England and "an outstanding example of famil physician and friend"—and of two former members o the council, Sir Walter Langdon-Brown and Dr. Wardro Griffith. Dr. Thomas Fraser, the direct representativ for Scotland, has retired after five years' valued servic and Dr. R. W. Craig, former Scottish secretary of th British Medical Association, has taken his place. Mr Duncan Macgregor has been appointed by the Priv Council to be an additional member of the council unde the Dentists Act, 1921.

At their meeting in May, continued the president, th council decided that in the consideration of their draf recommendations as to the curriculum a stage had bee reached when it might be desirable to consult some o those concerned with the medical curriculum in Canad and the United States.

"Thanks to the generosity of the Nuffield Foundation, who defrayed the cost of transport across the Atlantic, and of the Rockefeller Foundation, who defrayed the cost of living in the New World, this aspiration was fulfilled, and in the middle of September a delegation from the council, consisting of Dr. Bigger, Dr. Brocklehurst, Dr. Campbell, Dr. Cohen, and myself, with the registrar, crossed the Atlantic and visited the following medical schools: in New York the Long Island college of medicine, Cornell University medical college, New York University college of medicine, and Columbia University college of physicians and surgeons; the University of Chicago; the University of Michigan medical school, Ann Arbor; in Canada, the faculties of medicine in the University of Toronto and in McGill University; the Harvard University medical school in Boston; and the Johns Hopkins University school of

LEEDS

County of York, E. Riding.

North-west

Counties of Bedford (Luton B. and R.D., Dunstable B., Leighton Buzzard U.D.), Bucks (boroughs of Chepping Wycombe and Slough; U.D.s of Beaconsfield, Chesham, Eton, and Marlow; R.D. of Amersham, Eton, and Wycombe).

Berks (boroughs of Maidenhead and New Windsor; R.D.s of Cookham, Easthampstead, and Windsor).

Herts (except areas in Cambridge and N.E. London regions).

Middlesex (except area in N.E. London region).

London (Hammersmith (north of Goldhawk Road and Stamford Brook Road), Hampstead, Holborn, Islington, Kensington (north of Holland Park Avenue, Notting Hill Gate, and Bayswater Road), Paddington (north of Bayswater Road), St. Marylebone, St. Pancras, Westminster (north-east of Park Lane, north of Constitution Hill, Birdcage Walk, Great George Street, and Bridge Street).

North-east

Counties of Essex (except area in Cambridge region); Herts (Hertford B., U.D.s of Bishop's Stortford, Cheshunt, Hoddesdon, Sawbridgeworth, Ware; R.D.s of Braughing, Hertford, and Ware); Middlesex (Edmonton B., Tottenham B., Enfield U.D.); London (Bethnal Green, City, Finsbury, Hackney, Poplar, Shoreditch, Stepney, Stoke Newington).

County boroughs of East Ham, Southend-on-Sea, and West Ham.

South-east

Counties of Kent and East Sussex; London (Bermondsey, Camberwell, Deptford, Greenwich, Lambeth (east of Kennington Park Road, Brixton Road, and Brixton Hill), Lewisham, Southwark, Woolwich).

County boroughs of Brighton, Canterbury, Eastbourne, and Hastings.

South-west

Counties of Surrey and West Sussex.

Hampshire, Isle of Wight, Dorset (except area in Bristol region), Wilts (boroughs of Salisbury and Wilton; R.D.s of Amesbury, Mere and Tisbury, and Salisbury and Wilton).

London (Battersea, Chelsea, Fulham, Hammersmith (south of Goldhawk Road and Stamford Brook Road), Kensington (south of Holland Park Avenue, Notting Hill Gate, and Bayswater Road), Lambeth (west of Kennington Park Road, Brixton Road, and Brixton Hill), Paddington (south of Bayswater Road), Wandsworth, Westminster (south-west of Park Lane, south of Constitution Hill, Birdcage Walk, Great George Street, and Bridge Street)).

County boroughs of Bournemouth, Croydon, Portsmouth, and Southampton.

OXFORD

Counties of Berkshire (except area in N.W. London region), Buckingham (except area in N.W. London region), Northampton, and Oxford.

County boroughs of Northampton, Oxford, and Reading.

BRISTOL

Counties of Cornwall, Devon, Gloucester, Somerset, and Wilts (except area in S.W. London region).

County of Dorset (boroughs of Bridport and Lyme Regis; Sherborne U.D.; R.D.s of Beaminster, Bridport, and Sherborne); Isles of Scilly.

County boroughs of Bath, Bristol, Exeter, Gloucester, and Plymouth.

CARDIFF

The whole of Wales and Monmouth.

BIRMINGHAM

Counties of Hereford, Leicester (Hinckley U.D.), Salop, Stafford (except Burton-on-Trent C.B. and Tutbury R.D.), Warwick, and Worcester.

County boroughs of Birmingham, Coventry, Dudley, Smethwick, Stoke-on-Trent, Walsall, West Bromwich, Wolverhampton, and Worcester.

MANCHESTER

Counties of Cheshire (except area in Liverpool region), Lancashire (except area in Liverpool region), and Westmorland (except area in Newcastle region).

County of Derby (boroughs of Buxton and Glossop, U.D.s of New Mills and Whaley Bridge, and R.D. of Chapel-en-le-Frith).

County boroughs of Barrow-in-Furness, Blackburn, Blackpool, Bolton, Burnley, Bury, Manchester, Oldham, Preston, Rochdale, Salford, and Stockport.

LIVERPOOL

County of Cheshire (C.B.s of Birkenhead, Chester, and Wallasey; boroughs of Bebington, Congleton, and Crewe; U.D.s of Alsager, Ellesmere Port, Hoylake, Hoole, Knutsford, Lymm, Middlewich, Nantwich, Neston, Northwich, Runcorn, Sandbach, Winsford, and Wirral; R.D.s of Bucklow, Chester, Congleton, Nantwich, Northwich, Runcorn, and Tarvin).

County of Lancashire (C.B.s of Bootle, Liverpool, St. Helens, Southport, Warrington, and Wigan; boroughs of Crosby and Widnes; U.D.s of Abram, Ashton-in-Makerfield, Aspull, Billinge and Winstanley, Formby, Golborne, Haydock, Hindley, Huyton with Roby, Ince-in-Makerfield, Litherland, Newton-le-Willows, Ormskirk, Orrell, Prescott, Rainford, Skelmersdale, Standish with Langtree, and Upholland; R.D.s of Warrington, West Lancashire, Whiston, and Wigan).

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED NOV. 16

Notifications.—Smallpox, 0; scarlet fever, 1293; whooping-cough, 1696; diphtheria, 330; paratyphoid, 26; typhoid, 7; measles (excluding rubella), 4382; pneumonia (primary or influenzal), 625; cerebrospinal fever, 30; poliomyelitis, 15; polioencephalitis, 2; encephalitis lethargica, 3; dysentery, 70; puerperal pyrexia, 141; ophthalmia neonatorum, 60. No case of cholera, plague, or typhus was notified during the week.

The number of Service and civilian sick in the Infectious Hospitals of the London County Council on Nov. 13 was 957. During the previous week the following cases were admitted: scarlet fever, 57; diphtheria, 31; measles, 22; whooping-cough, 35.

Deaths.—In 126 great towns there were no deaths from enteric fever, 1 (0) from measles, 1 (0) from scarlet fever, 9 (1) from whooping-cough, 7 (0) from diphtheria, 63 (6) from diarrhœa and enteritis under two years, and 16 (3) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 11 deaths from diarrhœa and enteritis, Manchester 9.

The number of stillbirths notified during the week was 297 (corresponding to a rate of 33 per thousand total births), including 48 in London.

The scheme was based on the insurance principle, with contributions from employees, employers, and the government. The contributions were fixed at 3*s*. per week for men and 2*s*. for women, with employers contributing similar amounts on account of each employee. There was no means test.

The benefits were: medical treatment, medicines, and drugs; sickness benefits (males 20*s*., females 15*s*., and dependent children 3*s*. 6*d*. weekly, for maximum of 26 weeks); disablement pension (males 15*s*., females 12*s*. 6*d*.); old-age pensions (males 20*s*., females 15*s*.); widows' pensions (12*s*. 6*d*., rising to 15*s*. by 1944); orphans' pensions (7*s*. 6*d*. if last parent insured). A comparison with the Beveridge plan showed that Australian contributions would have been two-thirds of the British, but the benefits would have been proportionately less.

Why was the scheme abandoned? First, it was out of step with the individualistic Australian temperament. Medical practice in Australia in 1938 was very different from that of Britain in 1938. Much more so from that in Britain in 1911. Sir Walter Kinnear, who framed the Australian scheme on British lines, was not sufficiently influenced by the leaders of the friendly societies in Australia. Secondly, although the federal executive of the British Medical Association had agreed to a capitation fee of 11*s*. a year, and had agreed to a pledge of secrecy until the Bill had been presented to Parliament, there was widespread criticism from the rank and file of B.M.A. members.

The Bill was finally passed on the promise that a Royal Commission would recommend a capitation fee, the scope of treatment, and travelling expenses. But even this action did not still the criticisms that (*a*) remuneration on the basis of an annual capitation fee was much too low, and an insurance doctor would be forced to increase the number of his panel patients at the expense of his professional efficiency; (*b*) no provision was made for mothers and children or for the unemployed, the small-scale employers, and self-employed persons; (*c*) no provision was made for hospital services, specialist services, preventive medicine, for regulation of medical working hours, or for better distribution of doctors to places where their services are needed, but which were economically unattractive; (*d*) there was no coördination between clinical treatment and hospital and health services.

Thirdly, employers, employees, friendly societies, feminists, and farmers all had various objections to the Bill. The shadow of war was beginning to fall; a record defence expenditure was in the budget, and there was a widespread drought in the country. If a last straw had been needed it was the tragic crash of an air-liner which was conveying most of the members of the Royal Commission. There were no survivors of this crash, which also destroyed most of the important documents of the commission.

As late as 1943 a parliamentary joint committee on social security announced sentence. "On the evidence submitted there is," they said, "unanimous objection to national health insurance as contained in the Commonwealth National Health and Pensions Insurance Act, 1938. Special attention has been directed to the restriction of benefits to a particular income group, to the very limited health and social benefits, and to the absence of any provisions covering the dependants of an insured person. . . . Generally it is our opinion that the National Health and Pensions Insurance Act falls far short of any plan of social security adequate for the people of Australia, and this Committee does not favour the principle of national insurance for such a purpose. In view of the overwhelming weight of evidence we strongly advise that no action be taken to implement any of the provisions of this legislation in its present form."

Dr. G. Matthew Fyfe, M.O.H. for Fife, is to represent the Scottish branch of the Society of Medical Officers of Health on the advisory committee set up under the Scottish Water Act, 1946.

Dr. Catherine B. Crane has been appointed medical officer of health for the city of York, in succession to the late Dr. P. R. MacNaught, whom she served as deputy. According to the *Medical Officer* of Nov. 23, Dr. Crane is the first woman to receive the full appointment of M.O.H. for a county borough.

Reconstruction

THE REGIONAL AREAS

MINISTRY'S PROVISIONAL PROPOSALS

UNDER the National Health Service Act the Ministe of Health is required to determine the areas to be covere by the regional hospital boards administering th hospital and specialist services. So far as possible thes areas are to be such that the services can convenientl be associated with a university having a medical school and in determining their extent the Minister mus consult the bodies and organisations which appear t him to be concerned.

Accordingly Mr. Bevan has now prepared a statemen of his provisional views and has asked a wide range o professional and other bodies for their observations—to reach him by Dec. 15.

In so doing he points out that the size and extent o the areas must be determined primarily by their purpose "which is to provide an area adapted rather for th planning, coördination, and provision of hospital and specialist services than for the control and management of hospitals. The latter task will . . . be the function o hospital management committees. It follows that th areas can and should be comparatively large in population, and such that each has a natural university medical centre as a focal point."

In certain regions geographical or other circumstances "appear to render it necessary that for part of the area there should be set up a regional committee of the board with delegated powers and its own offices. The Minister has in mind such areas as Devon and Cornwall; Hampshire, Dorset, and Isle of Wight; North Lancashire and South Westmorland; and Cumberland and North Westmorland."

The boundaries of regional areas need not and will not prevent the free passage of patients from one area to another. "Indeed in some instances at the outset regional boards will become responsible for hospitals, &c., in their area which have belonged to and served communities in other areas, and which must continue to do so." However, the Minister thinks that wherever possible the boundaries of the regional areas should coincide with those of local health authorities, so as to secure the maximum of administrative efficiency. Except where other considerations must in his view clearly prevail, the proposed boundaries accordingly follow those of counties and county boroughs. "In some instances it appears that other important factors (e.g., association of the services with the appropriate medical schools, grouping of related hospitals under the same regional board) make it essential to cross local health authority boundaries in defining the boundaries of regional board areas. Here again the Minister has sought wherever possible to ensure that the proposed boundaries shall coincide with those of boroughs or county districts."

The following notes show the 14 proposed areas, grouped round 11 universities. It will be noted that London University is related to four regions.

NEWCASTLE

Counties of Cumberland, Northumberland, and Durham.

County boroughs of Carlisle; Newcastle-upon-Tyne and Tynemouth; Darlington, Gateshead, South Shields, Sunderland, and West Hartlepool.

County of Westmorland (Appleby B. and North Westmorland R.D.).

County of York, N. Riding (Middlesbrough C.B.; boroughs of Redcar, Richmond, and Thornaby-on-Tees; U.D.s of Eston, Guisborough, Loftus, Northallerton, Saltburn and Marske, and Skelton and Brotton; and R.D.s of Croft, Northallerton, Reeth, Richmond, Startforth, and Stokesley).

Letters to the Editor

REGIONAL BOARDS

SIR,—Sir Leonard Parsons and Sir Ernest Rock Carling have written most valuable letters on regional affairs.

A comment, however, seems called for on Sir Leonard Parsons's use of the words "administration" and "policy," which I think has also puzzled Sir Ernest Rock Carling. Referring to your leading article of Nov. 9, Sir Leonard Parsons asks whether you are right in assuming that the function of the regional boards is primarily one of administration. He says that in his view the boards should be concerned with "policy" whilst "administration" should be delegated to the hospital management committees. It is a misfortune that our terminology for dealing with such matters is so lacking in precision. One could be forgiven for supposing that "administration" and "policy" in this context were synonyms and not opposites—i.e., that policy means major questions of administration. And one would have thought that if the board were concerned with "policy" the implication would be that it should be predominantly lay and served by a lay chief executive officer as in the case of the board of a hospital.

Sir Leonard Parsons, however, argues that the prime concern of the regional board—its policy—should be to organise the best possible facilities for treatment, and he draws the conclusion that "it would follow" that the primary qualification of the chief executive officer of the board should be his "intimate knowledge of the medical aspects of hospital care." I hope this is a fair summary of his argument. In regard to the object of the board, one can whole-heartedly agree: in regard to method, and the question whether the objective is best achieved by a medical chief executive officer, there is room for difference of opinion.

The trouble is surely this: that if professional ability could really be brought to bear in the simple way Sir Leonard Parsons suggests, all would be plain sailing. There would in fact be no need for a regional board or of a medical advisory committee at all. A medical man acting as a commissioner would suffice. But in actual fact this is not the case: medical men differ as to what ought to be done, and a lay decision has to be taken somewhere and by somebody as to the allocation of monetary resources: hence the need for the machinery of the medical advisory committee and lay governing body on the lines on which it has evolved in our hospitals.

Sir Ernest Rock Carling suggests that in the matter of the chief executive officer there should be experiment—some regions trying a medical man and others a layman, if the right individuals can be found. The danger of the medical chief executive officer is not that he will be a worse servant to the board than the layman of corresponding experience and ability, but that he may arrogate to himself the functions of the medical advisory committee and ultimately render it an ineffective appendix to his own conception of "the medical aspects of hospital care." This is a real and serious danger which might well lead to a blurring of the distinction between lay "policy" on the one hand, and professional advice on the other. Policy and politics are not far apart, and it is of overriding importance that the profession should keep a firm grasp of its advisory relationship to the machinery of policy.

YOUR CORRESPONDENT OF NOV. 9.

CORONARY DISEASE

SIR,—In your issue of Nov. 9 Prof. J. A. Ryle trails his coat on the vexed question of the ætiology of coronary disease which Sir Maurice Cassidy raised in his recent Harveian oration. I am prompted to ask the Irishman's question: Is this a private (physicians') fight, or can anyone (even a surgeon) join in?

From my hilltop position of seniority the fence between medicine and surgery appears merely as an artificial aid to the cultivation of a continuous field. This letter is primarily an assertion of the right of any one branch of medicine to offer criticism and suggestion to any other branch. In the present era of multiple specialism the maintenance of this right is of vital importance to the future of medicine. It offers a guarantee against the danger that the corpus of medicine will be split up into a number of specialties having no more organic connexion or communication between themselves than the joints on a butcher's counter: there will result an extravagant devotion to technique, and a loss of interest in pathology, which necessarily deals with the body as a working whole.

I must pursue this long digression a little further to make my meaning clear, and to illustrate the fruitful interchange of ideas. Many years ago the late Dr. Essex Wynter asked me to see with him a case of ascites, and suggested that I should expose the femoral canal, open it, and drain the fluid into the subcutaneous tissue of the thigh. In carefully selected cases Essex Wynter's operation of "femoral drainage" has proved to be a permanent cure for ascites. Per contra, I have ventured into the field of dermatology to prove that lupus is essentially a tuberculous lymphangitis, and into that of urology to suggest that for unilateral prostatic enlargement a unilateral adenectomy will give permanent relief at a minimum of risk. These are just instances of what I mean.

To return to coronary disease and its increasing frequency. I have recently come across two cases in medical men where a long history of chronic cholecystitis preceded cardiac trouble, and I would ask whether a chronic bacterial infection of the liver, probably staphylococcal, since that organism is *par excellence* the organism of thrombosis, is not a more likely cause than the "strain of modern life." Professor Ryle and Sir M. Cassidy in their country journeys are certainly subject to less strain than was Sir Astley Cooper in his stage-coach, shouting to the postilion "I pay sixpence a mile for bad driving, ninepence a mile for good driving, and a shilling a mile if you drive like hell."

It must be significant that the classes who subject their cardiovascular mechanism to maximum strain by heavy work are not the selected victims of coronary trouble. Mental work may fray the nerves, but does it impose much strain on the heart and arteries? What it certainly may do by interference with regular meals, digestion, sleep, and exercise, is to upset the alimentary mechanism, and favour chronic infections, helped as age advances by a growing defect of thyroid activity.

An attack on the subject from this point of view, and by really intensive pathological and bacteriological examination of even a few cases post mortem, might, I venture to think, prove even more rewarding than the extensive statistical inquiries suggested by Professor Ryle.

London, W.1. W. SAMPSON HANDLEY.

ICTERUS GRAVIS NEONATORUM

SIR,—In his interesting paper of Nov. 2 Dr. Third makes certain statements which are open to criticism. For instance, he says, "There seem to be, however, three very distinct pathological types"—hydrops fœtalis, toxic jaundice, and erythroblastæmia—and adds, "It is undesirable to include all groups under either icterus gravis or hæmolytic disease, because not all cases are hæmolytic, nor are all cases severely jaundiced." From the description he gives, "erythroblastæmia" is clearly the condition usually known as hæmolytic anæmia of the newborn, and, apart from the fact that babies suffering from icterus gravis are always severely jaundiced (otherwise why is the disease called icterus gravis?), children in all these three groups, although not necessarily obviously anæmic, do show evidence of hæmolysis and at autopsy an erythroblastotic reaction thereto.[1] Erythroblastæmia is the result of this reaction and is in no sense evidence of a special variety of hæmolytic disease of the newborn; indeed, it is sometimes absent in that disease at birth, whereas it is sometimes present in the normal full-term infant, and both it and jaundice may be present in sepsis neonatorum and congenital syphilis. The best general name for the disease under discussion is either "hæmolytic disease of the newborn" or "congenital hæmolytic disease," since the more usual title "erythroblastosis fœtalis" refers only to the erythroblastotic reaction which at one time American workers thought was the cause of the disease. The names given to the

In England Now

A Running Commentary by Peripatetic Correspondents

Now is my time for stocktaking. Until a year ago my life was in the R.A.F., now it's in G.P. The differences are very great and the changing mind can play queer tricks. For instance, there is one hilly road leading into our valley town that I will drive down in preference to all the others. This gives a panoramic view of the town below, turns sharp right and immediately increases its angle of descent for 100 yards (A.S.I. 90–95 m.p.h.). Then it flattens suddenly for 10 yards (1st check), descends again almost to the valley bottom, eases left, then right, bumps over a railway bridge (throttle back and ease the stick forward), then over a canal bridge (throttle right back, ease the tail down), and glides straight in towards the main street (flap lever up, look behind you). Then, instead of setting the trimmer tail heavy, I change into second gear and turn into the main street. My first solo is over, but it will never be forgotten.

There were awkward moments when a modern youth would slouch into the surgery and say, "I wornt a milk ticket furr me Dad." He would look at me as if I were the Minister of Labour. And I would look at him for long enough to curdle the milk before it was delivered.

Other difficulties were over forgetting the patients' names. It's easy to connect the face with the complaint, but even the pioneer studies of Ebbinghaus didn't help, because if one was going to use the method of learning by groups and related series whole families would have to attend the surgery together. But within a week of our finding a permanent house near the centre of the town I could remember most of the names and even recall the names of those I had seen in the first month. Retroactive inhibition? Emotional blockage? I dunno.

* * *

To sit in the common-room of any strange university and discuss the current technical problems is always a pleasure. To do so in Germany brings to life the shadowy curtain of unreality that seems inseparable from everything to do with the country just now.

We had sat through a demonstration of the effects of starvation on children, put on for our special benefit. There was only one case of any importance. All comment about prognosis, and the difficulty of getting rid of famine œdema, was immediately scotched by a reference to our experiences at concentration camps.

We then learnt, with joy (and it must be admitted a good deal of disbelief), that a way had been found of converting soya bean into an almost tasteless milk. It has been converted into almost everything in its time, but never has the scientist succeeded in disguising its taste for long. It has even been detected in the non-soya sausage now issued in lieu of its more famous relative, the war-time link. We were not then surprised to find that, though palatable at first, second thoughts were unanimous in deciding that nature's milk was better. Still, it is a useful adjunct to protein-starved Europe.

It might be thought that these little interludes would prevent a friendly discussion of Germany's educational and spiritual problems. We were delighted to find that the eminent professors (now often youngsters since their elders, and usually betters, had failed to survive either Hitler's or our purge) were only too glad to talk. They were afraid of Communism because once again it removed the responsibility of thinking from the individual. That, they thought, was its main appeal to the youth of the country, and not its economic policy. They told us the story of the school-teacher who, after a lecture on Independent Thought delivered by an eminent British Parliamentarian, went up to the speaker and asked for some guidance on independent thinking. They then fell into the same mistake themselves by saying that we should show them how to govern. When we suggested that they should try to find out and that we would try to guide them, they were a little surprised.

It is pathetic how lost the whole nation appears to be. It is also a little frightening to realise how difficult it is to bring into being an entirely new method of thought. The danger is that someone will give them a new doctrine to follow before they have assimilated the new method of reasoning that we are attempting to instil into their politics. Most of the Germans at heart still believe that their cause was right, but that they were unlucky in not applying a better method.

Rather unexpectedly there is a great demand among German students for instruction in philosophy. And yet perhaps not so strange. The Dean had some misgivings about this, fearing that it was not a real thirst for knowledge but a method of escape, and perhaps of self-justification. He did not find a willingness to learn from the older men, a desire to draw from their experience. But perhaps the German student is no different in that from his colleagues all over the world. "Everyone wants to be a student," he said. "There are far too many of them. What Germany wants for the next twenty years is men that can use their hands." Looking at the almost untouched piles of rubble we were inclined to agree.

* * *

I am going to start a one-man war against our chi occupational disease, though I cannot look forward any Nobel award if I succeed. My only recompense w be in the fact that the medical profession are the chi sufferers. Slowly but surely this detestable complai jargon aphasia, eporrhœa, or Herbert's disease, h been invading our ranks from the chief endemic reservo of infection—the official circular. Typical cases, li the "disinfestation officer" who circulated a repo which suggested that mice should be trapped as the emerge from their apertures, are fortunately rare, b there is no lack of this kind of thing:

> "This failure to exercise objective acumen derives fro professional indoctrination with the time-worn diagnost axiom, that to seek a plurality of causes for a clinical pictu is deplorable. It is understandable that in a busy clini scientific curiosity may be curbed when the therapeut exigencies are abbreviated by the self-determined cour of the disorder. . . . The phenomenology observed followin ingestion of *Datura stramonium* seeds may be incorrectl interpreted as evidence of an affective disorder."
>
> "Pronation deficiency following immobilisation in plast can be minimised by taking care to avoid inversion of th foot, and to see that the foot is pronated in plaster as muc as possible."
>
> "The drug is devoid of risk, but irresponsible patient should preferably be institutionalised."

In the general presence of disease we may forget th look of health. "Sir, your son was struck in the leg b a cannonball, that we were forced to cut it off, whereo he died. . . ." ". . . that you be hanged by the neck unti you are dead, and the Lord have mercy on your soul.' Deformed as we are, of necessity, by the weight o sulphonamides, heteroauxins, heteronymous hemianopias and osteodystrophiæ epiphysio-arthriticæ, we can at leas raise our heads to look back at better days.

In the matter of words and units, the electricians, wh made themselves a vocabulary to measure, have the better of us. Their terminology, crisp, homely, and readily transferable into an alphabet of signs that recall gardening implements, is enviable to us—better than the rings and semi-detached indoxyl penthouses of the biochemists with their barbarous names. Could we not measure olfactory thresholds in snouts and megasnouts, the lateness of honorary physicians at rounds in dawdles or coffees? A terminology rugged but not barbarous, that is what we want. Let us take personal names if we wish, and to ohms and curies let us oppose chaplins of valgus deformity, potts of curvature, even megafreddies of azoospermia and charringtons of polyuria. We could well enrich the language which we are now occupied to outrage.

* * *

"Even my driver sometimes doesn't know what the diagnosis is." This startling remark by an UNRRA medical officer in Germany led to the explanation that his colleagues from among the Displaced Persons of Eastern Europe very naturally and rightly report their diagnoses in Latin, of which tongue he, being Western-trained, was comparatively ignorant. His Polish D.P. driver, an ex-medical student, had recently explained to him, for example, that "Intussusceptio ustii abdominalis" did not mean that D.P.'s had a bone in their bellies unknown in America!

of the last treatment. Then there followed a course of psychotherapy lasting over two years which terminated when I was called up for service with H.M. Forces. I have since been demobbed with my group and returned to my civilian job and there has been no relapse.

I do not pretend that E.C.T. is a pleasant experience; I was anxious about it, but " dread " would be the wrong word to use, and I would have it again if necessary. Apart from the pain in the back following the convulsions the experience was not too bad. One is knocked out immediately. But it must be pointed out that even psychotherapy is not altogether an enjoyable experience. After many stormy sessions one learns that, unlike E.C.T., *there is no anæsthesia !*

It seems a pity to exaggerate about E.C.T. Surely by now a sufficient number of cases have been examined, treated, and followed up by competent psychiatrists for its true worth to be assessed ? DOCTOR-PATIENT.

SIR,—Dr. Learoyd (Nov. 23) disapproves of convulsion therapy, and speaks of our mental hospitals as of Belsens within our gates. He is, of course, entitled to his views; yet, To offend, and judge, are distinct offices, And of opposed natures.

Truro. H. PULLAR-STRECKER.

EXERCISE AND CARDIAC HYPERTROPHY

SIR,—Sir Adolphe Abrahams's case of cardiac hypertrophy (Oct. 19, p. 565) in an otherwise normal man of 78, who was in his youth a successful long-distance cyclist, is of extraordinary interest. The old-established opinion of some clinicians that a normal heart never hypertrophies, now queried in this paper, is overdue for revision.

There is considerable evidence that such hearts are acquired and not congenital. Whole series of oarsmen and long-distance runners show, as I have been able to demonstrate,[1] hypertrophy which can be recognised in the X-ray picture at a glance. It would appear very unlikely that these men have become record-holders through having large hearts.

The main evidence is that the hearts of professional sportsmen show, in the rare cases that come to necropsy, typical hypertrophy, affecting only those parts of the heart which are heavily strained.[2] Apart from this, there is plenty of evidence from training experiments with rats and dogs that certain kinds of exercise cause hypertrophy. It should not be necessary, therefore, to preserve the myth that the normal heart does not hypertrophy. It definitely does, and the importance of the case published is that the hypertrophy persisted into old age—a possibility which, till now, has been doubted by many, including myself.

London, N.22. H. HERXHEIMER.

ARSENICAL ENCEPHALOPATHY

SIR,—Dr. J. R. Edge reports (Nov. 9) an interesting case of myocardial fibrosis ending in fatal heart-failure, in a man who had been treated with neoarsphenamine for early syphilis. After the second injection of his second course of treatment the patient passed into coma, and on recovering was left with permanent bilateral pyramidal signs.

The cardiac complication is unusual, and I would suggest that the encephalopathy is worthy of further comment. Arsenical encephalopathy in Europeans is a very rare condition of which I have only seen one example. During the late war it was however very common amongst Indian troops. In two large V.D. centres in India the incidence of encephalopathy over a long period was as high as 1 in 73 cases treated, and in another over several months the incidence rose to 1 in 55. This became a very serious matter as the mortality was invariably about 50 %.

The factors underlying arsenical encephalopathy are by no means clear. Dosage is only one factor, and I have seen a fatal outcome following a single injection of 0·3 g. N.A.B. Probably a more important factor is the relationship of dose to body-weight, and most cases of encephalopathy in Indians occurred in the undernourished: incidentally, they were almost invariably Tamils or Bengalis.

The clinical picture is essentially one of coma and convulsions, often of very rapid onset, but sometimes preceded for a few hours by confusion or other altered mental states. Focal signs are usually absent, and, apart from dilated and sluggish pupils with bilateral extensor responses when coma was deep, I was never able to elicit focal signs. Various forms of empirical therapy were tried (British anti-lewisite was not available), but none seemed to influence the course of the disease in any way. Among the 50 % who recovered, I did not observe any sequelæ. Dr. Edge's case is therefore unusual in that there were apparently no convulsions and neurological sequelæ were severe.

Dr. Edge refers to the commonest findings in the brains of fatal cases. Major L. Krainer, R.A.M.C., found however that in a large number of cases careful microscopy did not show any adequate cause of death, and certainly in those cases which were rapidly fatal histological examination was negative.

Leeds. HUGH GARLAND.

MALT EXTRACT IN INFANT FEEDING

SIR,—An investigation at the Lister Institute[1] has shown that a combination of malt extract, wheat flour, and soya flour, in which about 70 % of the total solids and about 30 % of the total protein is obtained from malt extract, possesses a mixture of proteins whose growth-promoting value for young rats is about equal to that of the protein of milk. It is also concluded that such a mixture, if used for baby food, would not need supplementation with food yeast or synthetic B vitamins.

Since these important findings may find direct application in the present food crises, it seems desirable to emphasise that malt extract can vary widely in composition, as shown by the following data obtained in these laboratories on a series of some 70 commercial malt extracts from over 30 different manufacturers, excluding samples fortified with synthetic B vitamins[2]:

		per 100 g. dry matter	
		range	*mean*
" Protein "	g.	1·30–8·37	5·31
Vitamin B_1	mg.	0·23–0·58	0·37
Riboflavin	mg.	0·27–0·50	0·42
Nicotinic acid	mg.	9·3–16·5	12·6

The so-called " protein " of malt extract (vide *B.P.* 1932), being obtained by the action of malt enzymes on the crude protein of germinated barley, contains digestion products of protein which are more readily available to the actively growing baby or young rat. This should be borne in mind when seeking an explanation for the marked improvement in the biological value of the protein mixture in 'Maltavena' produced by the relatively small proportion (perhaps about a third) which can come from malt extract. Moreover, the growth-promoting properties of maltavena will also depend on its content of B vitamins, by far the greater part of which should be derived from the malt extract. The malt extracts we used in manufacturing the maltavena supplied to Dr. Chick for her experiments had vitamin-B contents close to the maxima in the above table, and protein contents well above the average. We can imagine that if maltavena were made with less nutritious malt extracts it might not give such good results. It is therefore desirable that the manufacture of maltavena for infant feeding should, wherever possible, be controlled by estimation of the above factors.

We emphasised this point strongly when discussing the matter last year with Major McNeile, who was then in charge of brewing and distilling in the British zone in Germany; and we offered to undertake estimations on maltavena preparations which he was arranging to make in Germany. We have not had the opportunity of examining any of the maltavena preparations which have been used in Germany, mainly in the Dortmund area, and we sincerely hope that their contents of the above factors have been controlled by other workers, and that such control will be exerted in any future experiments.

Ovaltine Research Laboratories,
King's Langley, Herts.

FRANK WOKES

three subgroups are derived from the outstanding symptoms present in each group—œdema in hydrops; jaundice in icterus gravis; hæmolytic anæmia in hæmolytic anæmia of the newborn.

Again, Dr. Third states that the results of blood-transfusions "are satisfactory in true erythroblastæmia only. In the 'toxic jaundice' type there is grave risk that if the child recovers it will be faulty to the point of imbecility." If, in fact, this were the case it would be wise to withhold blood-transfusion and allow these babies to die. In a series of over 250 babies suffering from hæmolytic disease of the newborn treated at the Children's Hospital, Birmingham, the majority of whom had icterus gravis, kernicterus—as evidenced by autopsy findings or by clinical symptoms such as extrapyramidal rigidity, mental deficiency, &c.—occurred in about 7% of cases; moreover, the incidence of kernicterus was not decreased by the use of Rh-negative blood. Dr. Third mentions that he has been able to find evidence of "cerebral or extrapyramidal irritation" in the majority of babies with "toxic jaundice" which came under his care. I have, however, never been able to find convincing signs of this condition in newborn babies, although on rare occasions a high-pitched cry and convulsions have suggested that possibility to me. If I ever did find unequivocal signs of kernicterus in a newborn baby I should certainly abstain from any form of treatment and wish for its death.

Finally, it is true, as Dr. Third points out, that Rh antibodies have been found in breast milk, but the evidence that these have any ill effect on the child is, so far, insufficient to warrant artificial feeding in preference to breast-feeding, although it may be wise to express the breast milk and boil it before giving it to the child.

Birmingham. LEONARD G. PARSONS.

CALCIFEROL FOR TUBERCULOUS ADENITIS

SIR,—Recently there have been in THE LANCET a few reports on the treatment of tuberculous cervical adenitis with high doses of calciferol, with apparently satisfactory results. In the last 6 months my partner and I have treated five children with this condition. The first three were treated by rest and good food. In two of these the glands became fluctuant and were repeatedly aspirated, eventually breaking down; and in the third they slowly resolved and healed in about $3^1/_2$ months.

The last two children, a girl of 11 years and a boy of 3 years, had in addition to general treatment 100,000 units of calciferol daily for a month. There was no obvious change in the first week, and then they rapidly began to resolve—the temperature came down, the periadenitis subsided, and the glands lost their tenderness and rapidly became more discrete, firmer, and smaller. The girl's gland had healed in 4 weeks and the boy's in 6 weeks. The boy's mass had been very large and under other conditions one would have expected it to become fluctuant. These results seemed very satisfactory, and there were no side-effects of the treatment. Both children had a well-marked positive Mantoux test to 1/1000 old tuberculin.

In view of the satisfactory reports on a few scattered cases it would be interesting to know if anyone has treated a wider group, and more scientifically.

Rothbury, Northumberland. ANTHONY BELL.

LEFT TURN

SIR,—In his speech on the Act (*Brit. med. J.* Nov. 16, p. 747) Dr. Dain describes as dictatorship the position where the representatives of the people have the chief say in deciding the principles on which the new service shall operate. In its place he appears to advocate "government of the doctors, by the doctors, for the doctors" as the essence of democracy.

This curiously inverted attitude, reminiscent of Father William, is shared by quite a number of the older members of the profession and arises from refusal to accept the fact that there has been something of a change in the political complexion of the country. Doctors were formerly entitled to a specially privileged status as protégés of the ruling class, and many of them are unwilling to accept the loss of privilege which this change implies. Is it too much to ask the profession to stand on their feet instead of their heads? The profession should be content to be assessed by the public at its true worth by the contribution which it can make to society. It should seek an alliance with a rising working-class rather than with a decaying bourgeoisie.

Insistence on professional "dignity" is merely an effort to retain the benefits of patronage which obtained under squirearchy. This is the obstacle which has prevented the medical profession from following the example of the teachers and other workers and organising itself in a trade union. Such a step is the proper remedy for the situation, visualised by the British Medical Association spokesmen, of doctors under the new Act with no right of appeal to an independent body. By this means the medical profession could at once secure a proper recognition of its own services and make a useful contribution to democracy in practice.

St. Mary Cray, Kent. BRIAN H. KIRMAN.

LOCAL PENICILLIN IN CORTICAL MASTOIDECTOMY

SIR,—Mr. Philip Reading (*Lancet*, 1946, i, 811) has described a method in which a cortical mastoidectomy cavity is filled with penicillin dissolved in fluid plasma, which is then clotted by adding thrombin; the skin incision is afterwards sutured completely.

This method is a great advance in the technique of completion and aftercare of this operation. We have found, however, that obtainable fluid plasma does not always coagulate on adding thrombin. If citrated blood taken from the patient by venepuncture be used *instead of plasma, its clotting may lead to a bogg* swelling, due to serum, under the wound, and cau *suspicion of pus. Insufflating the operation cavity* wi penicillin powder and letting it fill with blood al has the disadvantage of not ensuring homogeneo distribution of the penicillin throughout the clot.

We have obtained results as satisfactory as those Reading by filling the operation cavity with a pas made by mixing penicillin solution with plasma serum powder, using approximately 100,000 units penicillin in each instance. A thorough operation an very good hæmostasis are essential to success. Complet primary suture of the skin wound is carried out. I cases suitable for cortical mastoidectomy middle-ea suppuration has usually ceased and the tympanic men brane and the wound heal within a week. Audiomet tests before and some weeks after operation show tha the hearing of patients thus treated is usually improve or unaffected by the procedure; this applies also t other methods of aftercare of cortical mastoidectomy.

Warwick. J. A. HARPMAN.

PSYCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—Dr. Glaister (Oct. 26, p. 615) claims tha intensive electro-convulsive treatment is ethically wron when applied to psychoneurotics but ethically righ when applied to sufferers from melancholia. Yet in bot types the fundamental personalities are intact, so wha is the ethical difference in treating both by electro convulsions?

The rigid distinction between the symptoms and th disease made by Dr. Glaister is hard to draw in psycho logical medicine. Is melancholia a symptom or a disease Are the whining, the egocentricity, and the misery o the psychoneurotic merely symptoms? If such a patient is made cheerful, coöperative, and happy, and remains so, is not this a cure of his disease, no matter how th cure is effected?

Even if there be a slight intellectual deterioration after treatment, the patient is still the gainer if he be made happy. Presumably happiness is what the patient wants.

Bridlington. P. D. H. CHAPMAN.

SIR,—When your correspondents begin to mention Belsen and livid pages in history, it is surely time for doctor-patients who are not psychiatrists to give their experiences. In 1941 I suffered from a psychosis characterised by depression and anxiety. After wandering about the grounds of a mental home for many weeks, having given up hope of following my profession again, and with no confidence in medical colleagues, I received 10 convulsions, and returned to full dut

All the new and expanded social service schemes must be considered as a coördinated whole and most of the difficulties which have arisen out of the piecemeal introduction of parts of the schemes will be removed when the full schemes are in operation. In the meantime, the Assistance Board have been considering the position of children in families drawing supplementary pensions or unemployment assistance. They have now submitted draft regulations embodying increases in their scale rates for children which have been accepted by the Government, and I propose to lay these draft regulations before Parliament this week.

Tuberculosis Allowances

Lieutenant-Commander Clark Hutchison asked the Secretary of State for Scotland whether it was his intention to introduce amending legislation so as to enable a person who was in receipt of a tuberculosis allowance to draw, if otherwise eligible, the allowance payable under the Family Allowances Act, 1945.—Mr. G. Buchanan replied: Recent social legislation has aimed at the principle of avoiding duplication of benefits payable out of public funds, but Mr. Westwood is in consultation with the Minister of Health about the possibility of increasing the rate for children under the tuberculosis allowances scheme.

Miners' Dermatitis

Replying to a question Mr. James Griffiths stated that the number of cases of dermatitis among miners generally, the majority of whom will have been coalminers, from 1938 to 1945 were as follows:

1938	254	1942	884
1939	305	1943	1207
1940	402	1944	1506
1941	573	1945	1867

National Health Service

Mr. Somerville Hastings asked the Minister of Health whether, in view of the public misrepresentations regarding the National Health Service Act, he would consider the issue to the public of a short factual statement setting out the main provisions of the Act.—Mr. A. Bevan replied: At the appropriate time before the service comes into operation I intend to make known as widely as possible the effect of the Act and the nature of the services to be provided under it.

Health Insurance Prescriptions

Dr. R. Clitherow asked the Minister if he was aware that prescriptions for dangerous drugs and scheduled drugs were being issued to National Health Insurance patients in quantities sufficient, in many cases, to ensure a constant supply for many weeks—namely, 200 barbitone tablets in one case; and if, in view of the possibility of the patient taking increasing doses and perhaps becoming an addict, he would take steps to prevent the issue of National Health Insurance prescriptions containing dangerous drugs and scheduled drugs for more than one week's supply at any one time.—Mr. Bevan replied: I do not think it would be proper to interfere with a doctor's discretion by any such general prohibition.

National Dietary Survey

Mr. P. Piratin asked the Minister of Food whether he would institute a national dietary survey to determine what changes in food consumption were needed to provide the whole population with a diet fully adequate for proper health.—Mr. J. Strachey replied: Since the beginning of the Second World War the Ministry of Food have conducted a national food survey of the diets of working-class households. They also make use of the surveys, clinical and otherwise, made by the Ministry of Health, the Department of Health for Scotland, and by research centres throughout the country. In the light of this information the Ministry of Food has followed a policy of providing, to the limit to which supplies are available, a diet adequate for proper health for the different sections of the community. In this they have been guided by the advice of the Ministry of Health and their own scientific adviser. In the circumstances no additional dietary survey is necessary.

Hospital Accommodation for Mental Defectives

Mr. R. W. Sorensen asked the Minister of Health what increase had been secured in accommodation for mental defectives during the past twelve months; to what extent mental hospitals were becoming overcrowded; and to what extent the number of nurses, trained and training, respectively had increased during the past twelve months.—Mr. Bevan replied: During the past twelve months the accommodation for mental defectives has increased by 177 beds; on Jan. 1, 1946, mental hospitals were overcrowded to the extent of 13,176 patients, or 11·5% of the total accommodation; the number of nursing staff employed in mental hospitals and mental-deficiency institutions has increased by 620 during the twelve months ended June 30, 1946, bringing the total to 25,840, just over half of whom are fully trained.

Obituary

CHARLES WILLIAM DEAN

F.R.C.S.E.

Mr. C. W. Dean, consulting surgeon and ophthalmic surgeon to the Royal Lancaster Infirmary, died on Nov. 15, only a few days after his 86th birthday.

Born in Lancaster, he spent his whole life there, apart from his student years in Edinburgh and at St. Bartholomew's Hospital in London. After qualifying L.R.C.P.E. in 1884 he was for the most part engaged in general practice, but he found time and opportunity to train himself in general and ophthalmic surgery. In 1899 he took the Edinburgh fellowship, and his work won the esteem and confidence of his neighbouring colleagues. He was the first surgeon in Lancaster to remove an appendix, and that was over fifty years ago.

"Dean never took part in public life," writes J. A. G., "but he was keenly interested in music, and in younger days he was no mean performer on the French horn. His taste in literature was wide. Belles-lettres, biography, and travel were probably most to his taste, and he had a more than superficial knowledge of heraldry. With a retentive memory, which time had not impaired, he had as he himself used to say 'a mind stored with useless and irrelevant facts,' which was perhaps one of the chief charms of his conversation. Quiet and reserved in manner, somewhat impulsive, very sympathetic, the feature of his character which most impressed me was his intense and essential humanness."

JAMES LAW BROWNLIE

M.D. GLASG.

Dr. J. L. Brownlie, who died in Edinburgh on Nov. 12, was a former chief medical officer of the Department of Health for Scotland, but probably his happiest days as a doctor were spent in the laboratory.

In 1913 he graduated M.B. at the University of Glasgow, and three years later took the D.P.H. at Cambridge. In 1918 he was awarded his M.D. with commendation for a thesis on the problem of the diphtheria carrier. After serving for some years in Glasgow corporation fever hospitals he became assistant bacteriologist in the city laboratory, and there developed his flair for epidemiology. From the Glasgow laboratory Brownlie went to take charge of the Lanarkshire public-health laboratory, and in 1930 he joined the staff of the Department of Health for Scotland. At first he was concerned with hospital and laboratory services, but in 1932 he became chief medical officer in succession to the late Dr. Parlane Kinloch. He was reluctant to assume the post, for he did not greatly enjoy the political flavour and the rough and tumble of work in a Government office, and the four years during which he held senior office were years of indifferent health, which finally compelled him to resign. A fellow of the Royal Society of Edinburgh, his interests were catholic and variously filled the years of his retirement. His many friends will remember his human qualities, generous hospitality, and shrewd commentaries on official vicissitudes.

IZSET MEAD HAYTHORNTHWAITE

L.R.C.P.E.

Dr. I. M. Haythornthwaite, who died on Nov. 24 at King's Langley, was the second woman to receive the Scottish Conjoint qualification. Born in 1859 and trained by the Zenana Bible and Medical Mission, she took the L.R.C.P.E. in 1886. After postgraduate study in Vienna she became in 1887 house-surgeon under Elizabeth Garrett Anderson at the New Hospital for Women, which then stood where Marylebone Station now is.

DETECTION OF TUBERCLE BACILLI IN C.S.F.

SIR,—A technique of concentrating tubercle bacilli in cerebrospinal fluids which I have applied to 24 specimens has been found to give a greater number of positive results than the usual methods. The technique can also be used for exudates and transudates which are not too viscid: the morphology of organisms is not affected. The method is as follows:

1. Place 3 c.cm. of C.S.F. in a 15 ml. centrifuge tube.
2. Add about 7 c.cm. of absolute alcohol, and cork with a rubber stopper; shake by inverting for two minutes, and allow to stand for thirty minutes.
3. Centrifuge at high speed for at least five minutes, and pour off the supernatant fluid, leaving the residue.
4. Add 10 c.cm. of distilled water, shake for two minutes, centrifuge at high speed for five minutes, pour off the supernatant fluid, mix well the residue with a fine capillary pipette, spread fairly thick on a slide, and let it dry.
5. Stain with Ziehl-Neelsen's stain and examine.

Public Health Department, Amman, Trans-Jordan.

B. S. N. SHAMYEH
Assistant Bacteriologist.

PENICILLIN FOR GONORRHŒA IN THE FEMALE

SIR,—Dr. Mascall (Nov. 16, p. 712) has sounded a long-needed warning against the indiscriminate use of penicillin for "gonorrhœa" in women, and his emphasis on the part played by the gonococcus and (I would add) allied organisms in the production of a "great amount of the chronic ill health from which so many women suffer" is sound. Many of us, however, have found penicillin of more value in treatment than any previous drug that has been tried—provided that it is used only in the right way. So far, in civilian practice, the penicillin-resistant gonococcus is fortunately a rarity, though this may not continue. At present the main cause of failure in treating gonorrhœa in the adult female is the lack of clinical diagnosis of minor degrees of extension of the disease to the body of the uterus and the adnexa. This may occur directly after the first menstrual period following the infection. The majority of female patients do not seek advice until that time, possibly because a woman often believes that her vaginal symptoms will clear up after her period. This delay gives time for the infection to ascend to regions where it becomes less accessible to drugs such as systemic penicillin. It is found that cure is difficult unless drainage is established by dilatation of the cervix and a glycerin drain, followed within twenty-four hours by the administration of the usual dosage of penicillin (i.e., 25,000 to 50,000 units three-hourly for four doses). In our hands the single "massive" dose has not yielded such good results. To ensure success, some such procedure as drainage followed by penicillin is essential in most of the cases. Patients seen and diagnosed within the first week of infection form the only exception.

For the intelligent use of penicillin in gonorrhœa (and in certain allied infections) clinical experience in gynæcological diagnosis is essential, and this is nearly always lacking in medical officers who have received special training only for "130 hours at an approved centre." Failures in treatment will persist until it is customary, for example, in each department, for every patient to be examined pelvically by the chief at least once a month and preferably more often.

Dr. Mascall also mentions the difficulties in the treatment of vulvovaginitis in children and with this we all agree. These difficulties can however be greatly reduced by treating these children only as inpatients in a unit where the nursing staff have been specially trained. While at home the child is often reinfected by the original source (even if every care is taken in the "follow-up" of contacts), and the average mother cannot carry out the necessary procedures to diminish infection from the child's garments, &c. The child's general health plays a large part in the cure of this disease, and the provision of good food, regular hours, and fresh air is a most important factor.

Our grateful thanks are due to Dr. Mascall for emphasising the high rate of failure in the treatment of gonorrhœa in the female by "routine" methods. The public have recently been lulled into the mistaken belief that there is an "easy" treatment of a potentially serious condition.

London, W.1.

G. M. SANDES.

Parliament

FROM THE PRESS GALLERY

Education of the Deaf

ON Nov. 20, on the motion for adjournment, Mr. EDWARD EVANS drew the attention of the House to the needs of those born deaf, of the deafened, and the hard of hearing. Mr. Evans, who for many years was the headmaster of a school for the deaf, pointed out that deafness imposed a greater educational and social handicap on healthy people than any other disability. A child born deaf had to learn by a laborious and lengthy process not only how to speak but also how to acquire language. Even then he seldom attained the fluency of a normally hearing person. It was of the greatest importance that a deaf child should receive as early as possible the benefits of special education, but there was a tragic dearth of nursery accommodation and places for infants.

Nearly all deaf schools were understaffed, and Mr. Evans urged the Ministry of Education to encourage ex-Service men and women to take up this work. Only one secondary grammar school was available for deaf children, and it was incapable of dealing with the demand for places, was inadequately financed, and lacked representative control. There was also, Mr. Evans declared, a need for a first-class technical school where other trades than the traditional ones of bootmaking, tailoring, and baking could be taught. He was convinced that in normal schools many backward children suffered from some form of deafness, and with proper training would develop educationally. To pick out these children as early as possible, a gramophone audiometer, he suggested, should be in use in every school for group-testing. The certification of deaf people as mentally defective, he continued, was an anxiety to all who were associated with their welfare. Most psychological tests depended upon linguistic response beyond the capacity of the totally deaf, and he felt strongly that no deaf person should be certified unless a trained teacher of the deaf or a welfare worker was present.

In his reply Mr. C. KEY, parliamentary secretary to the Ministry of Health, said that there were a goodly number of schools for the deaf—some 44—already in existence, but there was a growing appreciation of the problem, and conferences were being held in many areas to consider the provision of additional schools and the extension of existing ones.

Because so much publicity had been given to the scheme to provide hearing-aids free of cost under the National Health Service it did not mean that the Government believed hearing-aids to be the beginning and the end of the problem. The electro-acoustics committee was only one of three M.R.C. committees. Another was at work on the medical and surgical considerations for the diagnosis and treatment of deafness, and another was considering the education of deaf children and adults. In framing comprehensive measures for the deaf the Minister would be armed with authoritative recommendations from all three, and Mr. Key thought there would be no difficulty in persuading the Medical Research Council to undertake further research.

QUESTION TIME

Streptomycin Trials

Colonel D. E. CROSTHWAITE-EYRE asked the Lord President of the Council what provision had been made by his department for research into the use of streptomycin, and whether any moneys had been allocated for research and production of this drug.—Mr. HERBERT MORRISON replied: The Medical Research Council have arranged for making controlled clinical trials of streptomycin, as soon as supplies are available, to determine its value in tuberculosis and other conditions and the best methods of its use. Funds are being allocated for the cost of this work, including the purchase of the necessary quantities of the product.

Family Allowances Complaints

Mr. P. DAINES asked the Minister of National Insurance whether he would now state what action it was proposed to take as a result of the examination of the complaints arising out of the working of the Family Allowances Act, to which his attention had been drawn.—Mr. JAMES GRIFFITHS replied:

All the new and expanded social service schemes must be considered as a coördinated whole and most of the difficulties which have arisen out of the piecemeal introduction of parts of the schemes will be removed when the full schemes are in operation. In the meantime, the Assistance Board have been considering the position of children in families drawing supplementary pensions or unemployment assistance. They have now submitted draft regulations embodying increases in their scale rates for children which have been accepted by the Government, and I propose to lay these draft regulations before Parliament this week.

Tuberculosis Allowances

Lieutenant-Commander CLARK HUTCHISON asked the Secretary of State for Scotland whether it was his intention to introduce amending legislation so as to enable a person who was in receipt of a tuberculosis allowance to draw, if otherwise eligible, the allowance payable under the Family Allowances Act, 1945.—Mr. G. BUCHANAN replied: Recent social legislation has aimed at the principle of avoiding duplication of benefits payable out of public funds, but Mr. Westwood is in consultation with the Minister of Health about the possibility of increasing the rate for children under the tuberculosis allowances scheme.

Miners' Dermatitis

Replying to a question Mr. JAMES GRIFFITHS stated that the number of cases of dermatitis among miners generally, the majority of whom will have been coalminers, from 1938 to 1945 were as follows:

1938	254	1942	884
1939	305	1943	1207
1940	402	1944	1506
1941	573	1945	1867

National Health Service

Mr. SOMERVILLE HASTINGS asked the Minister of Health whether, in view of the public misrepresentations regarding the National Health Service Act, he would consider the issue to the public of a short factual statement setting out the main provisions of the Act.—Mr. A. BEVAN replied: At the appropriate time before the service comes into operation I intend to make known as widely as possible the effect of the Act and the nature of the services to be provided under it.

Health Insurance Prescriptions

Dr. R. CLITHEROW asked the Minister if he was aware that prescriptions for dangerous drugs and scheduled drugs were being issued to National Health Insurance patients in quantities sufficient, in many cases, to ensure a constant supply for many weeks—namely, 200 barbitone tablets in one case; and if, in view of the possibility of the patient taking increasing doses and perhaps becoming an addict, he would take steps to prevent the issue of National Health Insurance prescriptions containing dangerous drugs and scheduled drugs for more than one week's supply at any one time.—Mr. BEVAN replied: I do not think it would be proper to interfere with a doctor's discretion by any such general prohibition.

National Dietary Survey

Mr. P. PIRATIN asked the Minister of Food whether he would institute a national dietary survey to determine what changes in food consumption were needed to provide the whole population with a diet fully adequate for proper health.—Mr. J. STRACHEY replied: Since the beginning of the Second World War the Ministry of Food have conducted a national food survey of the diets of working-class households. They also make use of the surveys, clinical and otherwise, made by the Ministry of Health, the Department of Health for Scotland, and by research centres throughout the country. In the light of this information the Ministry of Food has followed a policy of providing, to the limit to which supplies are available, a diet adequate for proper health for the different sections of the community. In this they have been guided by the advice of the Ministry of Health and their own scientific adviser. In the circumstances no additional dietary survey is necessary.

Hospital Accommodation for Mental Defectives

Mr. R. W. SORENSEN asked the Minister of Health what increase had been secured in accommodation for mental defectives during the past twelve months; to what extent mental hospitals were becoming overcrowded; and to what extent the number of nurses, trained and training, respectively had increased during the past twelve months.—Mr. BEVAN replied: During the past twelve months the accommodation for mental defectives has increased by 177 beds; on Jan. 1, 1946, mental hospitals were overcrowded to the extent of 13,176 patients, or 11·5% of the total accommodation; the number of nursing staff employed in mental hospitals and mental-deficiency institutions has increased by 620 during the twelve months ended June 30, 1946, bringing the total to 25,840, just over half of whom are fully trained.

Obituary

CHARLES WILLIAM DEAN

F.R.C.S.E.

Mr. C. W. Dean, consulting surgeon and ophthalmic surgeon to the Royal Lancaster Infirmary, died on Nov. 15, only a few days after his 86th birthday.

Born in Lancaster, he spent his whole life there, apart from his student years in Edinburgh and at St. Bartholomew's Hospital in London. After qualifying L.R.C.P.E. in 1884 he was for the most part engaged in general practice, but he found time and opportunity to train himself in general and ophthalmic surgery. In 1899 he took the Edinburgh fellowship, and his work won the esteem and confidence of his neighbouring colleagues. He was the first surgeon in Lancaster to remove an appendix, and that was over fifty years ago.

"Dean never took part in public life," writes J. A. G., "but he was keenly interested in music, and in younger days he was no mean performer on the French horn. His taste in literature was wide. Belles-lettres, biography, and travel were probably most to his taste, and he had a more than superficial knowledge of heraldry. With a retentive memory, which time had not impaired, he had as he himself used to say 'a mind stored with useless and irrelevant facts,' which was perhaps one of the chief charms of his conversation. Quiet and reserved in manner, somewhat impulsive, very sympathetic, the feature of his character which most impressed me was his intense and essential humanness."

JAMES LAW BROWNLIE

M.D. GLASG.

Dr. J. L. Brownlie, who died in Edinburgh on Nov. 12, was a former chief medical officer of the Department of Health for Scotland, but probably his happiest days as a doctor were spent in the laboratory.

In 1913 he graduated M.B. at the University of Glasgow, and three years later took the D.P.H. at Cambridge. In 1918 he was awarded his M.D. with commendation for a thesis on the problem of the diphtheria carrier. After serving for some years in Glasgow corporation fever hospitals he became assistant bacteriologist in the city laboratory, and there developed his flair for epidemiology. From the Glasgow laboratory Brownlie went to take charge of the Lanarkshire public-health laboratory, and in 1930 he joined the staff of the Department of Health for Scotland. At first he was concerned with hospital and laboratory services, but in 1932 he became chief medical officer in succession to the late Dr. Parlane Kinloch. He was reluctant to assume the post, for he did not greatly enjoy the political flavour and the rough and tumble of work in a Government office, and the four years during which he held senior office were years of indifferent health, which finally compelled him to resign. A fellow of the Royal Society of Edinburgh, his interests were catholic and variously filled the years of his retirement. His many friends will remember his human qualities, generous hospitality, and shrewd commentaries on official vicissitudes.

IZSET MEAD HAYTHORNTHWAITE

L.R.C.P.E.

Dr. I. M. Haythornthwaite, who died on Nov. 24 at King's Langley, was the second woman to receive the Scottish Conjoint qualification. Born in 1859 and trained by the Zenana Bible and Medical Mission, she took the L.R.C.P.E. in 1886. After postgraduate study in Vienna she became in 1887 house-surgeon under Elizabeth Garrett Anderson at the New Hospital for Women, which then stood where Marylebone Station now is.

For the next five years she worked in the Lady Kinnaird Hospital for Women and Children with Miss Haskew (now Mrs. Birket), to whose efforts the building of that hospital was largely due.

Her marriage in 1892 to the Rev. J. P. Haythornthwaite put a term to her regular medical work, but while in Agra, from 1893 to 1911, as wife of the principal of St. John's College she found ample opportunities in ministering to the families of missionaries as well as in bringing up her own five children. In 1915 her eldest son was killed in action in France, and though by now she was getting old and somewhat infirm, she did her best to fill a place in the depleted ranks of doctors serving the civilian population. For short periods she worked as clinical assistant at the Garrett Anderson Hospital, and as resident medical officer at the Nayland Sanatorium For three years she was also visiting physician of the Four Boroughs antenatal clinic, and first doctor to the King's Langley antenatal clinic.

Her husband died many years before her; but she leaves three children, two of them doctors in India, who mourn the loss of a woman of more than ordinary character, ability, and sweetness.

E. P. H.

Diary of the Week

DEC. 1 TO 7

Tuesday, 3rd

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.1

5 P.M. Dr. H. L. Marriott: Quantitative Considerations Regarding *Depletion of Tissue Fluid and Blood Constituents.* (First Croonian lecture.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1

5.30 P.M. *Orthopædics.* Cases will be shown at 4.30 P.M.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2

5 P.M. Dr. G. B. Dowling: Erythrodermias.

Wednesday, 4th

ROYAL SOCIETY OF MEDICINE

2.30 P.M. *History of Medicine.* Dr. H. P. Bayon: Transition between Scholastic and Clinical Medicine in Europe during the 16th and 17th Centuries.

5 P.M. *Comparative Medicine.* Mr. H. H. Holman, PH.D.: Studies on the Hæmatology of the Horse, Ox, and Sheep. Mr. J. B. Brooksby: Serum Proteins of the Domestic Animals. Dr. C. L. Oakley: *Normal Constituents of Human Blood.* Dr. H. Grüneberg: *Inherited Disorders of the Blood in* Rodents.

8 P.M. *Surgery.* Pathological Meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, W.1

3.30 P.M. Prof. Arnold Sorsby: Blindness in Childhood—Past Achievements and Present Problems.

Thursday, 5th

ROYAL COLLEGE OF PHYSICIANS

5 P.M. Dr. H. L. Marriott: Quantitative Considerations Regarding Depletion of Tissue Fluid and Blood Constituents. (Second Croonian lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.2

5 P.M. Dr. B. D. Pullinger: *Cystic Disease of the Breast*—Human and Experimental. (Imperial Cancer Research Fund lecture.)

MEDICAL SOCIETY OF THE L.C.C. SERVICE

3 P.M. (North Eastern Hospital, St. Ann's Road, South Tottenham.) Cases will be shown. Dr. E. H. R. Harries: Modern Fever Hospital.

LONDON SCHOOL OF DERMATOLOGY

5 P.M. Dr. L. Forman: Cutaneous Manifestations of Malignant Disease.

CHADWICK PUBLIC LECTURES

4.30 P.M. (St. Mary's Hospital medical school, Paddington, W.2.) Prof. C. H. Stuart-Harris: Problem of Prevention of Acute Diseases of the Respiratory Tract, with Particular Reference to Influenza.

Friday, 6th

ROYAL SOCIETY OF MEDICINE

10.30 A.M. *Otology.* Cases will be shown at 10 A.M. Mr. Terence Cawthorne: Review of Surgery of Otosclerosis. Mr. Garnett Passe: Fenestration Operation. (Coloured film.)

2.30 P.M. *Laryngology.* Cases will be shown at 2 P.M. Miss D. J. Collier: Epistaxis. Mr. R. G. Macbeth: Ligation of Anterior Ethmoid Artery for Epistaxis.

5.30 P.M. *Anæsthetics.* Prof. H. N. Green, Dr. R. P. Harbord: Shock, with Special Reference to Anæsthesia.

BIOCHEMICAL SOCIETY

1.30 P.M. (National Institute for Medical Research, Hampstead, N.W.3.) Papers.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

8.30 P.M. (B.M.A. House, Tavistock Square, W.C.1.) Dr. W. Ritchie Russell: Rehabilitation after Head Injuries.

LONDON CHEST HOSPITAL, Victoria Park, E.2

5 P.M. Dr. Browning Alexander: Diagnosis and Treatment of Lung Abscess.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh

8 P.M. Colonel L. W. Harrison: Half a Lifetime in V.D.—from Chaos to Order.

Notes and News

MEDICAL WAR RELIEF FUND

DURING the past year 81 awards have been made from this fund at a cost of £18,016. The total amount distributed since the inauguration of the fund is now £52,236. Most of the applicants have been ex-Service doctors whose single-handed practices have declined seriously in their absence; other applications include ten from widows of doctors who lost their lives in the war. It is expected that further calls on the fund will be made by demobilised doctors needing help in resettlement, and by widows seeking the means to educate young children. The contributions received since the second appeal in December, 1945, amount to about £22,000. The committee hopes that those who have not yet responded will subscribe; cheques, payable to the fund, should be sent to the hon. treasurer at B.M.A. House, Tavistock Square, London, W.C.1.

ATOMIC WAR

Prof. Albert Einstein and a group of scientists have appealed for £250,000 to be used in educating the community in the social implications of atomic energy and the steps necessary to avoid the destruction of civilisation. The *Manchester Guardian* (Nov. 18) reports that the appeal is accompanied by the following declaration:

1. Atomic bombs can now be made cheaply and in large number. They will become more destructive.
2. There is no military defence against the atomic bomb and none can be expected.
3. Other nations can rediscover American secret processes by themselves.
4. Preparedness against atomic warfare is futile and if attempted will ruin the structure of our social order.
5. If war breaks out atomic bombs will be used and they will surely destroy our civilisation.
6. There is no solution to this problem except the international control of atomic energy and ultimately the elimination of war.

L.C.C. AND BOARDING-SCHOOLS

AT a meeting on Nov. 20 the L.C.C. education committee decided that a boarding-school education should be provided for children in certain categories. From September, 1947 the county council expects to have just over 200 places in direct-grant and independent schools. Selection will be made from: (1) orphans or neglected children, (2) children whose parents are unable to look after them, (3) children of parents living abroad, (4) children whose homes are moved frequently from one part of the country to another, and (5) children who live in congested areas. The education subcommittee take the view that, with the present restricted accommodation any attempt to place other children in boarding-schools, as envisaged recently by the Minister of Education,[1] should be deferred until these special categories have been dealt with.

TIERRA DEL FUEGANS

Prof. Alejandro Lipschutz, at a meeting of the Roya Anthropological Institute on Nov. 12, described the results obtained by a recent expedition to Tierra del Fuego. One o its objects was to determine whether the natives belonged to the general stock of American Indians or were descended from Australian immigrants. A great obstacle to the solution of this question was the fact that not only had the population dwindled from about two or three thousand a century ago to about two hundred today, but also miscegenation with Europeans had taken place to such an extent that only about a tenth of the Indians claimed to be of pure blood, and even their claims were very suspect. The blood-groups were determined in 77 persons, belonging to three very different tribes, and group O was found in about three-quarters of them pointing to the derivation of these three stocks from the general body of American Indians generally recognised as Mongoloid immigrants from Asia.

CANCER CONTROL IN LIVERPOOL

THE "unincorporated association known as Liverpool Cancer Control Organization" came into being on Feb. 3, 1939; it was not until March 23, 1945, that it received a certificate of incorporation. Thus its first report covers the work of six years. The two constant aims have been the concentration of resources and the establishment of a regional organisation based on Liverpool. In 1939 the city had four different stocks of radium, apart from that held privately, and two hospitals independently were conducting radiotherapy; surgical treatment was being undertaken in a large number of hospitals, and various separate bodies were interested in cancer control. Despite war-time diversions substantial progress has been made. The organisation has suggested that the Radium Institute should be amalgamated with the United Hospital, and that all X-ray therapy should then be concentrated in the institute as a branch of the United Hospital; this would mean that, when eventually the new United Hospital is built, its Radium Institute branch would take a place on the common site. This policy is approved by the National Radium Commission, and the plan has been under discussion by the parties directly concerned. Though the Cancer Act of 1939 will be superseded when the National Health Service Act comes into operation, the organisation, whose purposes are wider than those of the Cancer Act, expects to continue "to assist in combating the onset, progress, and effect of cancer, and to alleviate the sufferings caused by cancer."

SCIENTIFIC WHAT'S WHAT

In 1920 the Conjoint Board of Scientific Societies, acting on the suggestion of Sir Sidney Harmer, F.R.S., worked out a cheme for a complete list of scientific periodicals. When, in 923, the board was dissolved, the work was taken over by new non-profit company, under the chairmanship of the ate Sir Peter Chalmers Mitchell, F.R.S. With the help of donations from the Carnegie Trust and from private sources the first edition of the *World List of Scientific Periodicals* ppeared in 1925, and was followed by a second edition in 1934. This book, which names the place of publication and the ecommended abbreviation of over 33,000 periodicals and also gives the libraries where they are stocked, has proved nvaluable to scientists and librarians in and beyond Great Britain. For some time, however, it has been out of print, nd the council of management, under the chairmanship of Mr. S. A. Neave, D.SC., has decided to undertake a new edition, ncluding all periodicals published between 1900 and 1947. Librarians can help in the compilation of the list by sending particulars of journals either not included in the second dition or shown as having no location in this country. Communications should be directed to the secretary, World List of Scientific Periodicals, c/o the Zoological Society of London, Regent's Park, London, N.W.8.

BRITISH COUNCIL

THE council has had another active year. As might be xpected, European countries, such as Yugoslavia, are eager or news from Britain after their years of isolation; and there has been a heavy demand for medical books and periodicals.[1] The council has continued to publish its own medical journal, he *British Medical Bulletin*; it also runs a medical information service, helps to stock medical libraries, arranges for visits o Britain by foreign doctors and for overseas tours by British doctors, organises programmes for holders of the council's cholarships in medicine, and sponsors medical films. During he past years exhibitions of medical books have been held in arious countries, and Anglo-Chilean and Argentine-British medical centres have been opened. The council aims not only o interpret British ways to other countries but to promote our own understanding of foreign cultures; outside medicine his purpose was reflected in the exhibition here of paintings by Picasso and Matisse, and the interchange visits between he Old Vic company and the Comédie Française.

SENTENCE OF DEATH

FOR many years now the case for and against capital punishment has been debated in this country. In 1930 a select committee, in a majority report, recommended its uspension for an experimental period of five years; and the ssue will doubtless be raised again when the Government are able to introduce their Criminal Justice Bill. In the meanime, Mrs. Calvert has written a pamphlet in which the arguments for abolition are clearly set out.[1] Certainty of conviction and punishment, she says, is more effective in preventing crime than severity. When in 1810 Sir Samuel Romilly brought a proposal before Parliament to end capital punishment for shoplifting to the value of five shillings and upwards, Lord Ellenborough, the Chief Justice, said in the House of Lords' debate: "Such will be the consequence of the repeal of this statute that I am certain depredations to an unlimited extent would be immediately committed." The event proved him wrong. In eleven European countries, in parts of North and South America and Australia, and in New Zealand, the death penalty has been abolished or abrogated by disuse without influencing the trend of homicide figures. "It has," Mrs. Calvert concludes, "no place in a modern system of penal administration, and it is high time that it was swept away, and that the gallows took a place with the rack and the triangle in some limbo of obsolete instruments of punishment and torture."

University of Cambridge

At a congregation on Nov. 16 the following degrees were conferred:

M.B., B.Chir.—N. H. Harwood-Yarred, W. A. A. Hodges (by proxy); H. G. Mather.

University of London

Dr. John McMichael has been appointed to the university chair of medicine tenable at the British Postgraduate Medical School, as from Oct. 1, 1946.

Dr. McMichael is 42 years of age. He was educated at Kirkcudbright Academy and the University of Edinburgh, where in 1927 he was awarded the Eccles scholarship as the most distinguished graduate of the year. After holding house-appointments at the Royal Infirmary, Edinburgh, and at Paddington Green Children's Hospital, London, he returned to Edinburgh University in 1929 as Goodsir fellow to work in the departments of pathology and surgery. In 1930 he became M.R.C.P.E., and for the next four years he held a Beit fellowship, working first as assistant to the professor of medicine in the University of Aberdeen, and later as clinical assistant to Dr. J. W. McNee at University College Hospital, London, with whom he made a special study of the splenic anæmias. He was awarded a gold medal for his M.D. thesis in 1933. In 1934 he was appointed lecturer in human physiology in the University of Edinburgh, and in 1936 became Johnston and Lawrence research fellow of the Royal Society and extra hon. assistant physician at the Royal Infirmary, Edinburgh. He was elected F.R.S.E. in 1936 and F.R.C.P.E. in 1940. Since 1939 Dr. McMichael has been reader in medicine, and from the outbreak of the late war acting director of the department of medicine, at the British Postgraduate Medical School, London. Besides his work on the splenic anæmias, Dr. McMichael has published papers on hæmorrhage, shock, cardiac failure, and hepatitis.

Dr. S. D. Elliott has been appointed to the university readership in bacteriology tenable at the London Hospital medical college, as from Oct. 1, 1946.

From 1933 to 1935 Dr. Elliott was demonstrator in bacteriology, and from 1935 to 1937 assistant lecturer, at University College Hospital medical school. From 1937 to 1938 he was university demonstrator in pathology at Cambridge. Since 1938 he has been a Freedom research fellow in the department of bacteriology at the London Hospital medical college, from which he was seconded to the Emergency Medical Service during the war years. In February, 1941, he returned to the staff of the college, and was seconded to the Rockefeller Institute, New York, for six months.

University of Leeds

Mr. F. C. Happold, D.SC., reader in biochemistry, has been appointed to the chair of biochemistry, from August 1, 1946.

Mr. Digby Chamberlain has been appointed professor of surgery, from Oct. 1, 1946.

Mr. Chamberlain studied medicine at Leeds, where he qualified M.B., with first-class honours, in 1921. In 1924 he graduated CH.M., and became F.R.C.S. He was resident surgical officer and assistant surgeon at the General Infirmary before appointment to his present post as surgeon. He is also honorary visiting surgeon to a number of hospitals in and around Leeds. In 1921 he was awarded the William Hey gold medal by the University of Leeds, and in 1940 was Hunterian professor of the Royal College of Surgeons. He has taken special interest in abdominal surgery, on which he has published a number of papers.

The title of emeritus professor has been conferred on Prof. William MacAdam, Prof. P. L. Sutherland, and Prof. C. W. Vining.

University of Glasgow

Sir John Boyd Orr, M.D., F.R.S., has been elected chancellor of the university.

Royal College of Surgeons of England

The following lectures will be given at 5 P.M. during December: Thursday, 5th, Dr. B. D. Pullinger, Cystic Disease of the Breast, Human and Experimental (Imperial Cancer Research Fund lecture); Thursday, 12th, Mr. W. Rowley Bristow, Injuries of the Peripheral Nerves in Two World Wars (Robert Jones lecture); Tuesday, 17th, Mr. R. W. Raven, Melanoma and Related Tumours (Erasmus Wilson demonstration); and Thursday, 19th, Dr. E. Ashworth Underwood, Naval Medicine in the Ages of Elizabeth and John (Thomas Vicary lecture).

A course of 72 lectures on anatomy, applied physiology, and pathology will be given at the college between Feb. 3 and March 28, 1947, at 3.45 and 5 P.M. daily.

British Council, 3, Hanover Street, London, W.1. Annual report for 1945–46. Pp. 178.

Capital Punishment: Society Takes Revenge. By Theodora Calvert. Published by National News-Letter, 162, Buckingham Palace Road, London, S.W.1. 1s.

For the next five years she worked in the Lady Kinnaird Hospital for Women and Children with Miss Haskew (now Mrs. Birket), to whose efforts the building of that hospital was largely due.

Her marriage in 1892 to the Rev. J. P. Haythornthwaite put a term to her regular medical work, but while in Agra, from 1893 to 1911, as wife of the principal of St. John's College she found ample opportunities in ministering to the families of missionaries as well as in bringing up her own five children. In 1915 her eldest son was killed in action in France, and though by now she was getting old and somewhat infirm, she did her best to fill a place in the depleted ranks of doctors serving the civilian population. SYNOVIAL MEMBRANE AND SYNOVIAL FLUID OF JOINTS*

D. V. DAVIES
M.B. Lond.
LECTURER IN ANATOMY, UNIVERSITY OF CAMBRIDGE

LITTLE attention has been paid to the synovial membrane and synovial fluid of joints, although their mechanics have been discussed a great deal.

Paracelsus coined the term *synovia* or *synophia* for the fluid in joints (Hyrtl 1880). Among observations on the anatomy and physiology of joints are those of William Hunter (1743) on the blood-supply, the circulus vasculosus articuli; Bichat (1806) on the nature of the synovial membrane and the origin of the fluid; and John Hilton (1863) who enunciated what is now known as Hilton's law.

Recent contributions by Bauer and his colleagues (1930, 1940) have given accurate chemical analyses of both bovine and human synovial fluids. From the synovial mucin Meyer et al. (1939) have isolated its polysaccharide, which they term hyaluronic acid. Hoffman and Duran-Reynals (1930, 1931) and Chain and Duthie (1940) have isolated an enzyme, hyaluronidase, from animal and bacterial tissue capable of hydrolysing this mucin.

DEVELOPMENT

All the components of the diarthrodial joint are developed from mesoderm. The chondrifying skeletal elements, already sketched on the adult pattern, are at first separated by mesenchymal tissue, in which cavitation soon appears and delineates the joint cavity. The perichondrium is continued over the joint cavity as the capsule, while the lining of the cavity presents, on the one hand, articular cartilage and, on the other, synovial membrane. The capsule is composed of tough, inelastic, relatively avascular, white connective tissue with marked powers of resistance to disease and relatively low powers of repair. It differs but little from perichondrium or periosteum. The synovial membrane, on the other hand, is a soft, freely moving and elastic, sensitive membrane with a good blood-supply, good powers of repair and regeneration, and well-marked phagocytic powers. Accident, attrition, repeated trauma of the joint, and liability to certain infections (all forms of arthritis) focus attention on the vascularity and special function of the synovial membrane.

Special Features of the Diarthrodial Joint

STRUCTURE OF THE SYNOVIAL MEMBRANE

The synovial membrane forms a relatively smooth glistening yellowish or grey lining, covering all intra-articular surfaces except the cartilage-covered weight-bearing areas. It extends a few millimetres over the margin of the articular cartilage, adheres firmly to it, and terminates without any sharp line of demarcation. The contention of William Hunter (1743), upheld later by Bichat (1806), that it clothed the articular surfaces was rightly contradicted by Cruveilhier, Magendie, and Velpeau (Todd 1836).

The surface of the synovial membrane presents a variable number of folds and villi and, occasionally, delicate cord-like bridges, more often met with in bursæ. Information is still lacking about the extent of the synovial surface in various joints and its relation to the area of articular surface. Estimates of the synovial surface in the human knee- and ankle-joints show that, whereas the synovial membrane of the knee-joint is 43 sq. in., that of the ankle-joint is only 7 sq. in., but the cartilaginous surface of the ankle-joint is 5 sq. in. and that of the knee-joint only 23 sq. in.

The mobility and thickness of the synovial membrane depends on the quality and amount of the underlying subsynovial tissue and is adjusted to suit mechanical requirements. The underlying tissue may be abundant and loose in texture, the areolar type of Key (1928); dense collagenous tissue as at the articular margins or covering ligaments (fibrous type); or a pad of fat covered with a layer of synovial membrane in which the cells are more flattened (adipose type). Pads of fat are found in most joints and have in the past attracted much attention. Havers (1691) regarded them as mucilaginous glands. This view was rejected by Bichat (1806). MacConaill (1932) suggested that the freely movable pads of fat effected distribution of the synovial fluid. The extent and distribution of the areolar, fibrous, and adipose types of synovial membrane vary greatly from joint to joint; the temporomandibular joint, for example, is lined with a predominantly fibrous membrane, whereas the ankle-joint displays all three types, but predominantly the adipose and areolar.

The synovial membrane is relatively cellular, and its cells are pleomorphic, varying in their dimensions. There is little morphological similarity between the synovial membrane and the lining of serous cavities, such as the pleura and the peritoneum. The cells are often separated from the joint cavity by a homogeneous eosinophilic ground substance or even by collagenous fibres. The cells show a finely granular eosinophilic cytoplasm with occasional vacuoles or fat globules. Mitochondria are present as small granules or rods but display no constant orientation. The existence of a Golgi apparatus is denied by Key (1928) and Davies (1943) but described and figured by King (1935), who thinks that the orientation of the cell components is of functional significance.

Unlike pleura and peritoneum there is no basement membrane in the synovial membrane. Except at the transition zone of the articular margins, no cells resembling those of cartilage occur. Chondromatosis of the synovial membrane results from metaplasia and not from proliferation of pre-existing cartilage cells.

The statement that elastic tissue is sparse in synovial membrane is incorrect. A network of fine elastic fibres pervades most regions; this increases in amount in the more mobile areas and may form one or two distinct elastic laminæ (fig. 1). No elastic fibres occur in the villi except in association with the blood-vessels, and they are generally scanty over the fat pads. The elastic laminæ prevent the more mobile areas from being nipped between the articulating surfaces during motion.

NATURE OF SYNOVIAL CELLS

Much confusion exists as to the nature of the synovial lining. The cells are variously described as endothelial, epithelial, mesothelial, glandular, and, more latterly, as modified connective-tissue cells. The term mesothelial is the most informative. Pertinent questions are:

(1) Does the synovial lining differ from the underlying connective tissue and, if so, in what respects?
(2) Is the lining comparable with that of serous cavities, such as pleura or peritoneum?
(3) What rôle does the lining cell play in the economy of the joint, in production of synovial fluid or in its removal?

According to Vaubel (1933a and b) synovial cells differ from fibroblasts in tissue culture by their fibrinolytic activity and their ability to produce a mucin-like substance in detectable quantities. He suggests that they be designated synovioblasts. Further investigation with hyaluronidase might help to identify this mucin-like product obtained on culture. There is little similarity between normal synovial membrane and the lining of a false joint, where the lining layer consists purely of flattened connective tissue.

---

* An Arris and Gale lecture delivered at the Royal College of Surgeons on June 6, 1945.

Association of Anæsthetists of Great Britain and Ireland

As part of the centenary celebrations of the first administration of ether in Great Britain, a dinner-dance is to be held at the Dorchester Hotel on Saturday, Dec. 21.

Course in Industrial Medicine

A postgraduate course in industrial medicine is to be held at the London Hospital from April 21 to June 19, 1947. It will cover the syllabus for part II of the Royal Colleges' diploma in industrial health, and will include visits to factories. Applications should be sent to Dr. A. E. Clark-Kennedy, dean of the medical college, Turner Street, E.1.

Research into Effects of Nuclear Radiation

A Biological Research Division has been formed in the United States to investigate the effect of nuclear radiations upon living cells and to determine the maximum safe exposure. The division will include the following units: biochemistry, cytogenetics, general physiology, experimental radiology, and a section of coöperative studies. Observations will be based on radiations from nuclear disintegration within a pile.

Pharmaceutical Liaison Committee

This committee has been established to promote contact between the Ministries of Health and Supply on the one hand and the pharmaceutical profession on the other. The first meeting, under the chairmanship of Sir Weldon Dalrymple-Champneys, deputy chief medical officer of the Ministry of Health, was held on Oct. 16. The secretary is Miss C. Mozley-Stark, Ministry of Health, Whitehall, S.W.1.

New Laboratory for U.S. Institute

A laboratory for the study of infectious diseases has been added to the National Institute of Health, at Bethesda, Maryland, as a memorial to the 23 members of the U.S. Public Health Service who have died in the course of their work. The laboratory, which contains six research units, is to be directed by Dr. Charles Armstrong, chief of the division of infectious diseases at the institute.

Scientific Film Association

Two films from Australia (*Neurological Sequelæ of Deficiency Disease seen in ex-Prisoners-of-war*, and *Hydatid Disease of the Liver*) and one from Canada (*This Town is Ours*), which have been presented to the association, will be shown for the first time in Britain at 6 P.M. on Thursday, Dec. 5, in the film theatre of the Wellcome Foundation, 183, Euston Road, London, N.W.1.

Voluntary Work under the National Health Service Act

Speaking last week at Stratford, Mr. Charles Key, parliamentary secretary to the Ministry of Health, claimed that the scope for voluntary work will be just as wide in the future as it has been in the past. "Benefactors should not be put off," he said, "for this valuable outlet for benevolence will be made more attractive by the knowledge that money given to hospitals need no longer be used for their general expenditure. . . . The regional boards, the management committees, the house committees, and many other bodies will provide opportunities for those who wish to serve the public interest. Indeed, we hope that when the preoccupation with finance is removed . . . the scope for voluntary service will be greater than ever before."

Sound Waves to Kill Bacteria

High-frequency sound waves, vibrating at 100,000,000 cycles per second, are being used in the United States to destroy bacteria in food; they are stated to act by producing and rupturing a small air-bubble in the organism. Supersonic vibrations, says a B.U.P. message, have also been used to cut and drill teeth soundlessly and painlessly, though the process is at present too expensive for general application. Mr. Henry von Jenef, a Chicago acoustical engineer associated with the development of the process, claims that it has opened a new field in physical, chemical, and biological research since the sound waves are able to agitate and vibrate chemicals without heating them.

Return to Practice

The Central Medical War Committee announces that Dr. R. J. Buxton has resumed civilian practice at 34, Clarence Road South, Weston-super-Mare, Som.

In announcing on Nov. 2 the formation of a medical committee to advise the Government on the revision of the international list of the causes of death we inadvertently omitted the name of Prof. Arthur Ellis, F.R.C.P.

Appointments

AGASSIZ, C. D. S., M.C., M.D. Aberd., F.R.C.P., D.P.H.: medical superintendent, Queen Mary's Hospital, Carshalton.

COYLE, C. D., M.B. N.U.I.: medical superintendent, Archway group of hospitals, Highgate.

CRAWFORD, J. M., M.D. Edin., D.P.M.: deputy medical superintendent, Darenth Park.

DOUGLAS, A. A., M.D. St. And., F.R.C.S.E., D.P.H.: assistant ophthalmic surgeon, Children's Hospital, Birmingham.

FELDMAN, W., M.D. Lond., M.R.C.P.: medical superintendent, St. Giles' Hospital, London County Council.

FERRABY, G. S., M.S. Lond., F.R.C.S.: deputy medical superintendent, St. Charles' Hospital, London County Council.

HARDING, H. E., D.M. Oxfd: orthopædic surgeon, National Hospital, Queen Square, W.C.1.

INNES, A., M.B.E., M.B. Camb., F.R.C.S.: assistant orthopædic surgeon, Children's Hospital, Birmingham.

KING, A. J, M.B. Lond., F.R.C.S.: director and consultant venereologist, Whitechapel Clinic.

LEEBODY, J. G., M.B. Edin., F.R.C.S.E.: medical superintendent, Fulham Hospital.

LEONARD, F. R., M.B. N.Z., F.R.C.S.: deputy medical superintendent, St. Leonard's Hospital, London County Council.

LILLIS, W. J. P., L.R.C.P.I.: deputy medical superintendent, Western Hospital, London County Council.

MACDONALD, R., M.B. Edin., D.P.M.: first assistant medical officer, St. Lawrence's Hospital, London County Council.

MCEVOY, N. R., M.R.C.S., D.P.H.: assistant M.O.H., Dudley.

MARTIN, R. N., M.B. Belf., F.R.C.S.E.: orthopædic surgeon, St. Bartholomew's Hospital, Rochester.

MASCALL, W. N., M.R.C.S.: medical director, Endell Street Clinic.

MICHIE, E. J. M., M.B. St. And.: senior assistant M.O.H., Aberdeenshire.

MILLOY, J. M., M.B. Glasg., F.R.C.S.: medical superintendent, St. Mary Abbots Hospital.

MOORE, S. H., M.B. Dubl.: medical officer in Colonial Service, Hong-Kong.

PRICE, H. C., M.R.C.S., D.P.H.: deputy M.O.H. and tuberculosis officer, Fulham.

REID, J. C., M.D. Edin.: medical superintendent, Princess Mary's Convalescent Home, Margate.

RIDEHALGH, F., M.B. Camb., M.R.C.P.: chief clinical tuberculosis officer, Leeds.

RONALDSON, G. W., M.D. Glasg., D.P.H.: medical superintendent, Eastern Hospital, London County Council.

SAVORY, M., M.B. Camb., F.R.C.S.E., D.O.M.S.: ophthalmic surgeon, South London Hospital for Women.

TOWNSLEY, G., M.D. Belf., F.R.C.S.: surgeon and radiotherapeutic surgeon, St. Bartholomew's Hospital, Rochester.

WALSH, M. A., L.R.C.P.I., D.P.M.: first assistant medical officer, Tooting Bec Hospital.

WILSON, M. M., M.B. Leeds, D.P.H.: medical officer, Ministry of Education.

Births, Marriages, and Deaths

BIRTHS

FRANKLAND.—On Nov. 21, in London, the wife of Dr. A. W. Frankland—a daughter.

GRIFFITHS.—On Nov. 14, at Chester, the wife of Dr. F. E. Davidson Griffiths—a son.

HATFIELD.—On Nov. 15, at Ongar, the wife of Dr. F. E. S. Hatfield—a daughter.

HEWER.—On Nov. 20, in London, the wife of Dr. A. J. H. Hewer—a son.

HOLT.—On Nov. 17, at Stamford, the wife of Dr. Leslie R. Holt—a daughter.

JOY.—On Nov. 16, at Frome, the wife of Dr. David Joy—a daughter.

MCLAUGHLIN.—On Nov. 21, the wife of Mr. Redmond McLaughlin, F.R.C.S.E.—a daughter.

MITCHELL.—On Nov. 11, at Trieste, the wife of Lieutenant-Colonel P. C. Mitchell, M.C., R.A.M.C.—a son.

PRICHARD.—On Oct. 9, in London, the wife of Dr. J. S. Prichard—a daughter.

SQUIRE.—On Nov. 17, at Solihull, the wife of Dr. J. R. Squire—a daughter.

MARRIAGES

JAMES—WITHERS.—On Nov. 16, at Egerton, Flying-Officer Derrick William James, M.R.C.S., to Elisabeth Courtenay Wright Withers.

O'BRIEN—LEWIS.—On Nov. 5, in London, Daniel James O'Brien, M.B., to Margaret Mary Lewis.

RIDDELL—WILTSHIRE.—On Nov. 16, at Folkestone, Athol G. Riddell, M.B.E., M.B., to Valerie C. Wiltshire.

DEATHS

BOSWELL.—On Nov. 17, at St. Boswells, Henry St George Boswell, M.B. Edin., aged 89.

CAMPBELL.—On Nov. 15, at Castleford, John James Williamson Campbell, L.R.C.P.E., aged 84.

DEAN.—On Nov. 16, at Berkhamsted, Charles William Dean, F.R.C.S.E., aged 86.

GRIFFITHS.—On Nov. 16, at Cardiff, Thomas Elliss Griffiths, M.B. Lond.

LOCKE.—On Nov. 19, at Sedlescombe, George Locke, M.R.C.S., aged 93.

MACGILLIVRAY.—On Nov. 20, at Bad Salzuflen, Germany, Isabel Margaret MacGillivray, M.B. Edin., M.R.C.P.E.

MACPHAIL.—On Nov. 6, in Edinburgh, Alexandrina Matilda Macphail, O.B.E., L.R.C.P.E.

PUTTOCK.—On Nov. 10, at Billingshurst, Reginald Puttock, M.B. Camb.

SEARLE.—On Oct. 29, George Percy Searle, L.R.C.P.E.

WINTER.—On Nov. 20, at Rotherham, Herbert Edmund Winter, M.R.C.S., lieut.-colonel R.A.M.C., aged 85.

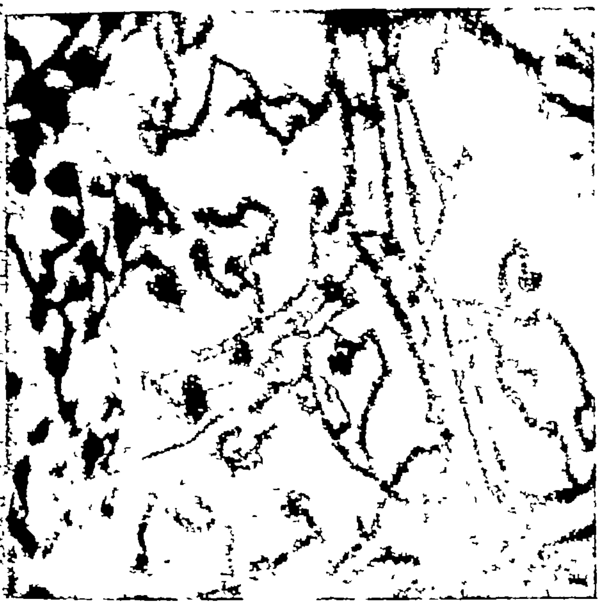

Fig. 4—Fresh synovial membrane from metatarsophalangeal joint of an ox, showing lymphatic vessels injected with Indian ink.

plexuses have been described. This plexus forms wide-meshed irregular polygonal patterns within which are seen numerous blindly ending vessels with terminal moniliform enlargements (fig. 4). The lymph vessels are neither so numerous nor so superficial as the blood capillaries, and no lymph vessels can be traced into the villi of the synovial membrane. The larger lymph vessels draining this plexus pass in groups of twos and threes along the blood-vessels towards the flexor aspect of the joint and communicate freely with the periosteal lymphatics (fig. 5). Few valves are seen in the synovial lymph vessels, but they are numerous in the collecting trunks on the periosteum. The plexus is finer and wider-meshed in the more fibrous types of synovial membrane. The effect of movement on the emptying of the synovial lymphatic vessels is made evident in trying to preserve specimens after injection.

EXCHANGE OF SUBSTANCES ACROSS THE SYNOVIAL MEMBRANE

The exchange of substances across the barrier of the synovial membrane is determined to a considerable extent by the arrangement of the arteries, veins, and lymphatic vessels. Solutions and substances of small molecular dimensions pass through the barrier with rapidity in either direction, mainly if not exclusively through the blood capillary bed. Colloidal particles of larger dimensions, including the proteins, reach the cavity more slowly, and their removal is slower still. This removal takes place by way of the blood capillary and lymph capillary streams. Particulate matter of 100 mm. and more moves slowly into the subsynovial tissue and becomes deposited there, moving no further (Key 1926, Adkins and Davies 1940). After hæmorrhage, hæmosiderin tends to accumulate here in considerable quantities (fig. 6). Exchange across the synovial barrier is increased in acute inflammation (Bauer et al. 1940), but the effects of chronic inflammation seem variable.

In the removal from the joint cavity of particulate matter the synovial cells and phagocytes of the synovial membrane play an important rôle. The rôle of the synovial cells in the exchange of solutions and small colloidal particles is dubious. Though most investigations show that a passive rôle is probable, there are some outstanding anomalies, such as the difference in rates of diffusion of thiocyanate and sugar, recorded by Bauer et al. (1940), and the failure of passage of methyl orange from the blood into the fluid in Engel's experiments (1940). It is probable that differing substances have different rates of transfer across the membrane, and these may differ from joint to joint. There are as yet no comparative data available as to the nature of these differences.

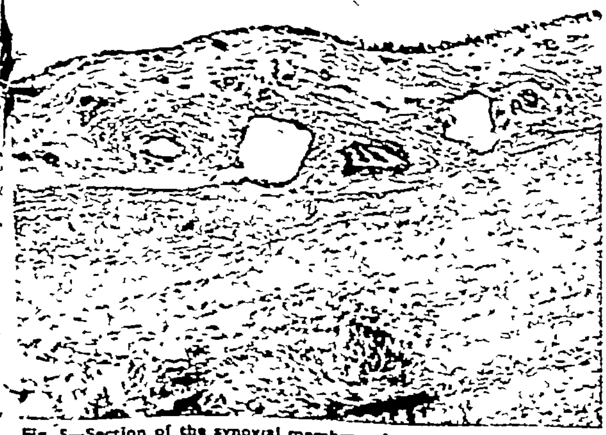

Fig. 5—Section of the synovial membrane from metatarsophalangeal joint of an ox, showing two large lymphatic vessels. Note valves in intervening vein. (×101.)

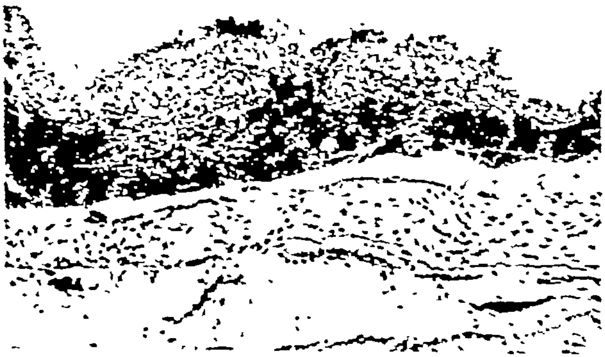

Fig. 6—Section through synovial membrane from a case of torn medial meniscus, showing a collection of hæmosiderin immediately beneath the surface. Stained for iron by the Prussian-blue reaction. (×85.)

Synovial Fluid

The physical characters of synovial fluid vary not only from animal to animal but also from joint to joint in the same animal. Its volume shows well-marked species differences which bear little relation to the size or capacity of the joint in question. The human knee-joint generally contains a small volume (0·2–0·3 c.cm.) of pale straw-coloured fluid of moderate viscosity, whereas the smaller knee-joint of sheep or dog contains a similar volume of highly viscous colourless fluid. In the ox the knee-joint contains about 10 c.cm. of fluid, whereas the ankle-joint has on the average 25 c.cm. and sometimes considerably more. Its viscosity bears no relation to the volume. In the ankle-joint of the ox the fluid is pale yellow and has a relative viscosity of about 5 at 20° C, whereas in the atlanto-occipital joint of the same animal the fluid is generally deep yellow and often sets into a gel at 20° C. Serial changes in character of the synovial fluid are shown in the costovertebral joints of cattle. The fluid is of greatest volume and smallest viscosity in the most anterior joint and progressively decreases in volume and increases in viscosity on passing backwards.

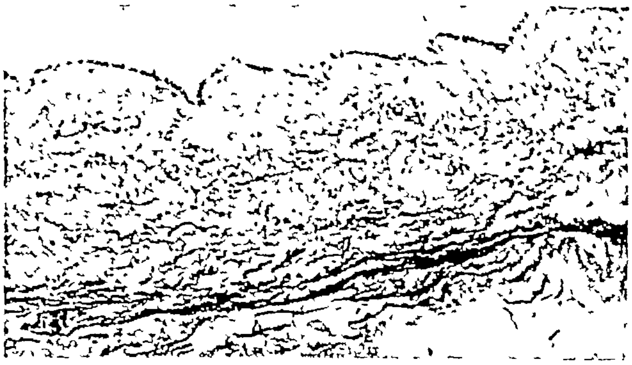

Fig. 1—Section of synovial membrane, from atlanto-occipital joint of an ox, stained with orcein to show elastic lamina. (×85.)

Synovial cells bear little resemblance to the flattened polygonal cells of peritoneum, although both show analogous changes in their response to irritation. They increase in number, enlarge, and retract their processes to become more rounded. According to Cunningham (1922) fibroblasts respond to irritation by becoming more elaborately branched. Synovial cells in small numbers are continually set free in the joint cavity. Their subsequent fate and functions remain obscure.

Key (1925) describes a re-formation of the synovial membrane, after synovectomy, by metaplasia of the underlying connective tissue. Whether the newly formed lining shows reactions analogous to normal synovial cells, and whether the contents of the joint cavity are in any way modified after this procedure, are important problems which remain unsolved.

NERVE-SUPPLY

John Hilton's (1863) statement still remains the most important pronouncement on the nerve-supply of joints:

> "The same trunks of nerves, whose branches supply the groups of muscles moving a joint also furnish a distribution of nerves to the skin over the insertions of the same muscles and—what at this moment more especially merits our attention—the interior of the joint receives its nerves from the same source."

Chief among the features of the synovial membrane is its sensitivity to pain. Localisation is often not highly accurate. To what degree the synovial membrane responds to other sensations, such as tension or pressure, is uncertain. Medullated and non-medullated nerves entering the joint with the blood-vessels form a plexus in the synovial membrane. The non-medullated fibre large part innervate the blood-vessels and are of sympathetic origin. The effects of sympat on the vascular supply of joints remain obscure in view of the paradoxical effects recorded by (1941), need investigation. The synovial mem and its villi show an abundance of free nerve-en presumably subserving pain; end-organs, p concerned with proprioceptive impulses, are described as of the Ruffini, Golgi, Mazzoni, lc knotted types. Pacinian corpuscles are not a char istic feature of the synovial membrane. Gardner (l failed to find them in the capsule, and I confirm Of the articular cartilage William Hunter (1743) said:

> "Insensibility of the articular cartilage is wisely con as by this means the necessary motion of the body performed without pain."

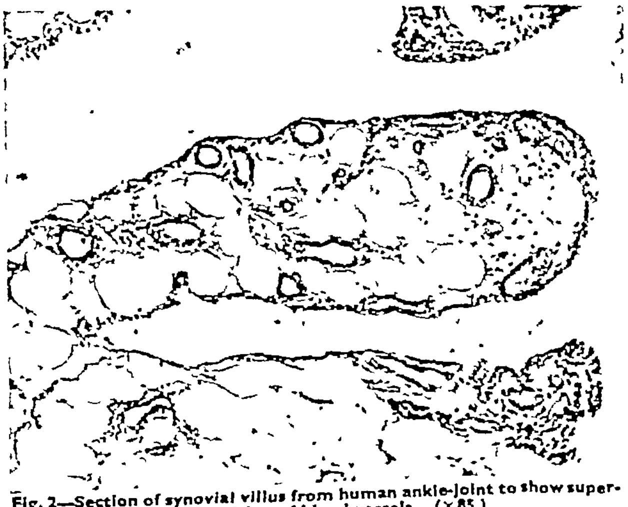

Fig. 2—Section of synovial villus from human ankle-joint to show superficial position of blood-vessels. (×85.)

BLOOD-SUPPLY

Little has been added to the first description of circulus vasculosus articuli by William Hunter in 174

> "All round the neck of the bone there is a great number Arteries and Veins, which ramify into smaller Branches communicate with one another by frequent Anastom like those of the mesentery. This might be called the Cir articuli vasculosus, the vascular border of the Joint."

The capillaries of the synovial membrane are characterised by their richness and superficial position (fig. 2). Small extravasations of blood into the joint cavity are very often found in animals, and some extravasation follows such a simple procedure as puncture (Davies 1944).

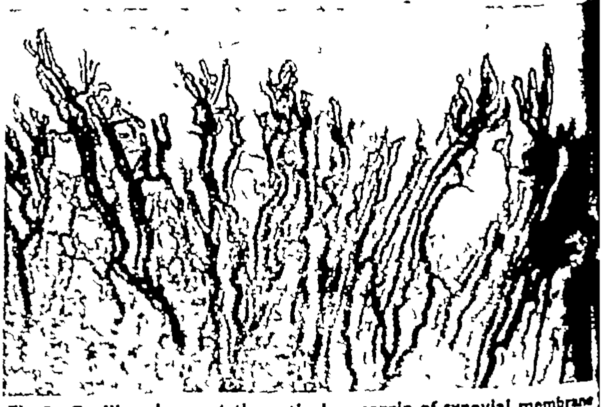

Fig. 3—Capillary loops at the articular margin of synovial membrane in talocalcaneal joint of a man in whom the corresponding femoral artery had been ligated. (×16½.)

At the articular margins the capillaries form delicate anastomosing loops comparable in pattern to those seen in the mesentery (fig. 3). In the villi and fringes the capillaries form delicate tufts supplied by one or more central arterioles. The blood-supply of synovial membrane and capsule communicates freely with the periost and epiphysial supply; hence the shaft of the bo forms one nutritional unit, and the joint cavity and the adjoining epiphyses form another. For this reason Harris (1933) uses the term *circulus vasculosus articuli et epiphyseos* to emphasise the nutritional interdependence of the joint and the epiphyses.

The venous drainage has received little attention. Sappey (Testut 1880) stated that the veins were characterised by their frequent anastomoses, tortuosities, and varicosities. Testut (1880) remarked on their voluminous nature. Occasional valves are seen in the larger veins, even in the more superficial parts of the synovial membrane (fig. 5).

LYMPHATICS

There is only one plexus of lymph vessels in the synovial membrane, though both superficial and deep ssues. Some regard the synovial fluid as the liquid atrix of the joint "tissue," if the cells here merit such name. If the mucin is derived from the matrix of the nnective tissue, it should contain both sulphated and n-sulphated mucopolysaccharides in the proportion which they exist in this tissue. The great variations hich are found in mucin content and viscosity from joint joint are opposed to such a view. Vaubel (1933a d b) has shown that synovial cells in tissue culture aborate a mucin-like substance, but its exact identity unknown. It is, however, a product of cell activity, asing to be produced when the synovioblasts are ansformed to fibroblasts or degenerate. Removal of ynovial fluid from normal joints in cattle is followed ithin less than twenty-four hours by the outpouring nto the cavity of an equal or even larger volume of a luid of high nitrogen content, rich in cells, and of low viscosity. This fluid is less viscous than the normal luid but differs from serum in the presence of mucin. t is probable that raising the viscosity to the normal [illegible] is a slow process and related to further elaboration f mucin by synovial cells. We do not know of any imulus which will increase the mucin content of the fluid.

FUNCTIONS OF THE SYNOVIAL GLAND

These may be summarised as follows:

(1) *Lubrication.*—This is clearly important but not ecessarily the main function. The amount of fluid in ost joints, including even the human, is in excess of t required for lubrication.

) *Nutrition*, particularly of the avascular articular lage.

Maintenance of a *constant fluid medium* within the The water binding power and high osmotic pro- es of mucin are essential to this. The hyaluronic of the mucin and the mucin itself are markedly roscopic.

) Maintenance of a *constant chemical reaction* within the joint. Both the mucin and the calcium are well ited to maintain the reaction of the synovial fluid at a onstant level.

(5) *Protective.*—Mucin in other organs has been shown o protect the tissues against enzyme action and toxins. hough no work has been done on this aspect of synovial nucin, there is reason to believe that it possesses similar rotective functions.

RELATIONSHIP OF
BENIGN LYMPHOCYTIC MENINGITIS AND GLANDULAR FEVER*

Sir Henry Tidy
K.B.E., M.D. Oxfd, F.R.C.P.
CONSULTING PHYSICIAN, ST. THOMAS'S HOSPITAL, LONDON

Glandular fever was originally described by Pfeiffer in 1889 as an acute infectious disease of children, characterised by rapid painless swelling of the cervical glands, in which suppuration never developed, with slight constitutional symptoms. Hæmaturia alone was noted as an occasional complication. The course was short and uniformly favourable.

Benign lymphocytic meningitis was first clearly described by Wallgren (1925) under the title "acute aseptic meningitis." The principal criteria given for the diagnosis were: (1) an acute onset of meningeal symptoms; (2) the absence of any condition known to cause meningeal irritation and of any acute or chronic infection; (3) changes in the cerebrospinal fluid (C.S.F.) characteristic of meningeal irritation, with an increase in the number of cells, especially lymphocytes, but no organisms; (4) a short mild course of the disease, with no complications; (5) the absence in the community of any disease which characteristically involves the central nervous system.

It is at first sight a far cry between these two supposed entities. Both conditions, however, have extended their boundaries beyond their original conception. Thus, benign lymphocytic meningitis has become linked with certain cases of meningo-encephalitis, of encephalitis, of lesions of the cord, and lesions of peripheral nerves. Glandular fever has extended even more widely. It became temporarily almost a blood disease with the recognition of the mononucleosis in 1920. The discovery of the presence in the blood of heterophil antibodies to sheep's red corpuscles, in which the disease is unique, established the existence of one entity without excluding the possibility of more than one virus. Other clinical and pathological manifestations have been added. Eruptions were found to be not infrequent and may be indistinguishable from rubella or may closely simulate many of the exanthemata. The blood-count at the onset may exhibit a well-marked polynucleosis or a leucopenia or be within normal limits. The long obscure febrile types were gradually recognised (though still often overlooked) in which several weeks may pass with constitutional symptoms only before a slight enlargement of lymphatic glands appears, with a late development of mononucleosis and heterophil agglutinins. This severe febrile type was found to be of almost any duration, short or long. This group, in which the characteristic glandular enlargement is slight and easily overlooked and the constitutional symptoms are more prominent, is of special interest for the question with which we are here concerned.

REVIEW OF PUBLISHED CASES

Epstein and Dameshek (1931) and Johansen (1931) gave the first clear descriptions of neurological complications in glandular fever. It is not intended to give here a review of all published cases but only to refer to those which illustrate the general picture.

Epstein and Dameshek's patient was a young man aged 19 years. The onset was sudden, with headache, malaise, and nausea. Five days later he had become stuporose and restless. On admission to hospital the temperature was 103° F. The C.S.F. was under pressure and contained 34 cells per c.mm., of which 30 were lymphocytes. In subsequent examinations the cells were all lymphocytes. In four weeks all symptoms had passed and the C.S.F. was normal. So far this is the

---

* Glandular fever and infectious mononucleosis are regarded as synonyms.

In many animals the volume seems to be greatly in excess of that required for lubrication (Davies 1944).

The chemical composition of the synovial fluid is still imperfectly known. Bauer and his colleagues regard synovial fluid as a dialysate of serum with added mucin. Apart from the proteins of the blood, urea, uric acid, and amino-acids seem to diffuse freely into the joints. Glucose is found in a lower concentration than in blood, a fact to be explained partly by the consumption of glucose within the joint.

Besides mucin, the synovial fluid contains albumin and globulin, with a predominance of albumin (in a proportion of about 4 : 1), but both in smaller concentration than in serum. This fits in with the greater permeability of the synovial barrier to the smaller albumin molecule. No fibrinogen is found in the synovial fluid. Hence the fluid does not clot, though the mucin may display a "spontaneous" precipitation in sac-like manner on standing (Davies 1944).

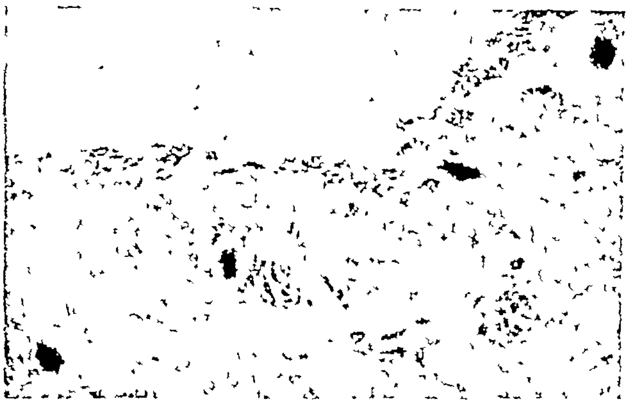

Fig. 7—Section of synovial membrane from ankle-joint of an ox, stained with polychrome methylene-blue to show the metachromatically stained mast cells. (×85.)

The proportions of electrolytes in the fluid are in accord with the Donnan equilibrium theory and resemble closely those in an ultrafiltrate of blood. Compared with serum, there is excess of chloride and bicarbonate, with lower concentrations of sodium, potassium, and magnesium and a similar concentration of inorganic phosphate. The calcium values are high, varying from 6·5–7·0 mg. per 100 c.cm. in the ankle-joint of the ox to 8·0–10 mg. in the atlanto-occipital joint. The calcium concentration is proportional to the mucin content and viscosity of the fluid, part of the calcium being bound to the mucin. The calcium may assist in maintaining the stability of the colloidal systems in the joint and with the mucin may form the main buffer system to keep the fluid alkaline (pH 7·5–7·7).

Apart from these observations there is no information on the variations in chemical composition from joint to joint, but it is certain that the cellular content differs widely.

The synovial mucin is distinct from the sulphate-containing mucins which are found in cartilage, gastric secretions, and ovarian cysts. *It is a sulphate-free mucin,* the viscous polysaccharide component of which has recently been isolated by Meyer et al. (1939) as hyaluronic acid, and found to be identical with the mucopolysaccharide of the vitreous of the eye and of Wharton's jelly in the umbilical cord. The same polysaccharide has also been identified in connective tissue, certain groups of streptococci, and certain tumours. Hyaluronic acid is a substance of high molecular weight, does not dialyse through collodion membranes, is highly viscous, forms salts with the amino groups of various proteins, is non-antigenic, is precipitated by acetic acid, and is apparently identical in all animals. In connective tissues it exists along with a sulphur-containing mu saccharide, probably chondroitin sulphuric acid. viscosity of hyaluronic-acid preparations is decre destroyed by many agents. An enzyme, hyalur which is found in high concentration in testicular and certain other tissues and bacteria, destroys th cosity of hyaluronic acid, then destroys its charact precipitability with acetic acid, and finally hydrol with the liberation of reducing substances. Hyaluro also reacts, though not so vigorously, with some sulphur-containing mucopolysaccharides.

There exists a great deal of uncertainty rega the staining reactions of synovial mucin. It is dou whether, like many other mucins, it stains chromatically with dyes, such as toluidine blue thionin. Lison (1935) reports that metachro staining is obtained with esters of sulphuric acid of molecular weight. I could detect no difference in staining reactions of synovial tissues with these after incubation with the hyaluronidase preparat and I suggest that the polysaccharide does not ex the metachromatic properties characteristic of sulphate-containing mucins and heparin (fig. 7).

CELL CONTENT OF SYNOVIAL FLUID

There are few observations on the cell conten human synovial fluid. Coggeshall et al. (1940), autopsies on 29 human knee-joints aged 32–80 y give a cell count ranging from 13 to 180, with an ave of 63 cells per c.mm.

Studies of the cell content in cattle, sheep, and h show several points of interest. The content of nucle white cells varies considerably from joint to joi the same animal—e.g., in cattle from about 200 per in the appendicular to about 1200 in some of th joints. The count varies from species to species an age within the same species. These variations are wholly explicable in terms of functional differe In general, in cattle the higher cell counts were obta in joints with highly viscous fluids and a marked free from disease and degenerative changes, such as thos the atlas (Davies 1945). Red blood cells do not norm occur in synovial fluid, though small traumatic ex vasations from the delicate capillaries are frequent.

Of the cell types, monocytes form about 50% of total, accompanied by rather fewer clasmatocytes, remainder being lymphocytes, polymorphonuclear le cytes, synovial cells, and unclassed phagocytes. Th is a significant variation in the proportions of th different types from joint to joint and species to spe This field remains unexplored.

THEORIES OF THE ORIGIN OF SYNOVIAL FLUID

That the fluid is more than a transudate is obvi from its mucin content. It cannot be a product degeneration in cartilage, for the mucin of cartilag distinct from that of synovial fluid. Theories that a secretion of certain areas or cells of the synovial n brane in the main depend on the demonstration patches of secretory cells. Havers (1691) thought t the synovial fluid was secreted by the synovial membr over the pads of fat, a view no longer tenable. mucin-secreting cells of the synovial membrane descri by Fisher (1923), Kling (1938), and others are b on metachromatic staining methods. I have inve gated these claims and concluded that the me chromatically staining cells in the synovial membra are mast cells; and, if any function is attributable them, it is that of maintenance of fluidity of the tiss juice. They certainly do not secrete mucin.

Chemical considerations indicate that the synovia a dialysate of blood plasma with the addition of muci The mucin may arise as a secretion of the synovial ce or a product of the intercellular matrix of the synovi andular fever must be looked for carefully, purposely, nd repeatedly, in view of the observations recorded bove. Only thus can glandular fever as an ætiological actor be excluded. Therefore it is pertinent to inquire ow far the published records of cases of benign lymphocytic meningitis give evidence of such examinations. h a search which is not claimed to be exhaustive I have iled to find a single published case in which glandular ever or infectious mononucleosis is even mentioned, much less excluded. Here and there are provoking statements. In the fatal case of Viets and Warren 1937) it is recorded that the white-cell count fell from 7,300 to 8650 per c.mm., but no other information is given. In the first case of Dominic (1937) the leucocyte-count is given as 11,300 per c.mm. (polymorphs 52%, ymphocytes 38%, Türk cells 10%); this might have been the early stage of a mononucleosis.

So far as this literature is concerned, every published case of benign lymphocytic meningitis may have been glandular fever; there is no evidence to exclude it. Naturally one does not put the claim for the association of the two conditions nearly so high as this. Many viruses may become neurotropic. One may note that the virus of glandular fever is probably not far removed from that of rubella; a point worthy of recollection in view of the recent discoveries of the effects of rubella. Writers on the neurological manifestations of glandular fever have almost invariably called attention to the close resemblance to benign lymphocytic meningitis. Epstein (1935) put the position quite clearly. But it must be recorded that Thelander and Shaw (1941) stated that they had seen many cases of benign lymphocytic meningitis and of encephalitis in children which they were certain were not connected with infectious mononucleosis; the evidence is not given.

It is hoped that in future those who diagnose benign lymphocytic meningitis will take all reasonable steps, in accordance with the principles set out above, to ascertain if glandular fever is the causal factor. Cases in which such examinations and observations have not been made cannot be put forward to support the claim that benign lymphocytic meningitis is an entity. At present there are apparently no others to support this view.

SUMMARY

The clinical symptoms, course, and prognosis of benign lymphocytic meningitis and of the neurological manifestations of glandular fever are indistinguishable.

The changes in the C.S.F. are identical in the two conditions.

In glandular fever with neurological manifestations the glandular enlargement is usually slight. This feature, together with mononucleosis and heterophil agglutinins, may only develop after the neurological symptoms have subsided, or may precede the nervous stage.

With the presence of such neurological symptoms, glandular fever can only be excluded by specific and repeated examinations.

Such examinations do not appear to have been performed in general in cases recorded as benign lymphocytic meningitis, and the possibility of glandular fever as a causal factor has consequently not been excluded.

FLUORINE HAZARDS

WITH SPECIAL REFERENCE TO SOME SOCIAL CONSEQUENCES OF INDUSTRIAL PROCESSES

MARGARET M. MURRAY
D.Sc. Lond.
LECTURER IN BIOLOGICAL CHEMISTRY AT BEDFORD COLLEGE FOR WOMEN, IN THE UNIVERSITY OF LONDON

DAGMAR C. WILSON
M.D. Glasg., M.R.C.P., F.R.C.O.G., D.P.H.
FROM THE INSTITUTE OF SOCIAL MEDICINE, OXFORD

IN this country the relation of certain industrial developments to human ecology is not as yet sufficiently appreciated. While it is a part of their function to ensure that the laws relating to the health of workers and public amenities are not infringed, it is not a special duty of Government departments to anticipate new industrial hazards or their secondary social effects.

An outbreak of fluorosis in cattle has once more drawn attention to the large amount of fluorine and fluorine compounds being set free by some recently extended industrial processes and has shown the necessity for consideration of the dangers to public health and to agricultural economy existing in the neighbourhood of these undertakings. At least 28 occupations provide the possibility of such dangers (Sappington 1943). In one industry alone, the manufacture of superphosphate fertilisers, more than 4400 tons of fluorine are "wastefully emptied" into the atmosphere of the British Isles annually (Gill 1946), though methods are known for the control, and in some cases for the further utilisation, of the fluorine liberated. Hazards associated with such fluorine evolution concern not only workers inside the factories but also their families living in the neighbourhood and others resident or employed in the area. They may also have economic consequences through damage to crops and animal stock.

Fluorine is derived from certain volcanic rocks and many different geological formations containing phosphates. Commercially, the main English source of fluorine is fluor-spar (calcium fluoride), but for the special purposes of aluminium manufacture cryolite (sodium aluminium fluoride) is imported from Greenland. In human nutrition fluorine is recognised as having a dual rôle, probably beneficial at one level of intake and definitely harmful at another. As a trace-element, the concentration at which fluorine is effective suggests a catalytic effect and/or an inhibitor action on certain enzyme systems. Epidemiological investigation in the United States, combined with standardised grading of dental fluorosis (mottled enamel), showed less dental caries and more teeth of good structure, with a "mild" degree of white mottling (Dean 1944) among people who had used drinking-water containing fluorine 0·5–1·0 part per million (p.p.m.) for at least the first eight years of life. With higher fluorine levels, staining of the enamel and skeletal changes may develop. In human balance experiments the close correlation between fluorine in the drinking-water and in the urine indicate that elimination of absorbed fluorine is practically complete when the quantity absorbed does not exceed 5 mg. daily (McClure et al. 1945). The provision of the right amount of fluorine in British water-supplies is a matter worthy of further study (Murray and Wilson 1945). Naturally occurring or endemic fluorosis, attributable to water-supplies, and "man-made" fluorosis, due to industrial processes, should be separately considered, though some of their effects may be the same.

In fluorine intoxication the effective poisons are the gaseous fluorine compounds or the fluorine ion; and, whenever fluorine tolerance levels are exceeded, systemic illness and bone abnormalities may develop. Fluorine can affect bone at all ages, leading in man to osteosclerosis, whereas tooth structure can only be influenced during record of a case of benign lymphocytic meningitis. But it was noted on admission that there was general glandular enlargement and the spleen was palpable. The leucocyte-count was 22,000 per c.mm., with 71% mononuclears.

In this case the ordinary manifestations of glandular fever and those of involvement of the meninges were present together and subsided simultaneously.

Johansen's case was materially similar, but in his patient there was no glandular enlargement.

Sucher and Schwarz's (1936) patient was a girl aged 17 years. The onset was with headache and vomiting. Slight glandular enlargement and a palpable spleen were noted a few days later, and there were ataxia, diplopia, and stiffness of the neck. The symptoms were not severe, no lumbar puncture was performed, and in a fortnight she was convalescent and the glands and spleen had subsided. The highest leucocyte-count was 14,000 per c.mm. (lymphocytes 80%). Ten days later the temperature rose again and some glands were palpable; the leucocyte-count was 9300 per c.mm. (polynuclears 65%). In the next fortnight she passed through stages of convulsions, coma, status epilepticus, left hemiparesis, and right oculomotor paralysis to practically complete recovery. The C.S.F. on more than one examination was under increased pressure and contained more than 100 cells per c.mm., all lymphocytes. Throughout this second period of well-marked neurological symptoms the leucocyte-count remained normal—e.g., 7000 per c.mm. (76% polynuclears).

In this case the characteristic features of glandular fever had appeared and subsided before the severe affection of the nervous system became manifest, during which period the blood-count was normal.

The Paul-Bunnell reaction for heterophil agglutinins was now coming into use, and is recorded in all subsequent published cases of neurological manifestations in glandular fever except Gsell's (1937). The reaction has been positive in the blood in all instances except the two cases in sisters, published by Thelander and Shaw (1941). It has never been positive in the C.S.F.

Landes et al. (1941) record the case of a man aged 21 years, whose illness began with severe pains in the calf, lasting twenty-four hours only, followed by headache, vomiting, giddiness, and unsteady gait. He became irritable and lethargic. On admission to hospital on the tenth day he was almost stuporose and speech was difficult to understand. There was no neck-rigidity. The C.S.F. contained a high excess of protein but only 5 cells per c.mm., all lymphocytes. Encephalitis was diagnosed. The leucocyte-count was 11,000 per c.mm. (polynuclears 50%, mononuclears 50%). The pathologist recognised that many types of mononuclear cells were present, and the Paul-Bunnell reaction was positive in a titre of 1 : 1024. By the twenty-second day the patient had lost all symptoms. On this day glands were felt in the neck and groin for the first time, though previously examined for regularly. On the twenty-fifth day the leucocyte-count was 10,100 per c.mm. (mononuclears 78%).

Landes considers that the diagnosis in this case would have been overlooked had not the pathologist tested for heterophil agglutinins. The neurological manifestations suggesting encephalitis had completely subsided before the glands enlarged.

Thelander and Shaw (1941) admitted a man, aged 22 years, with the diagnosis of meningitis. The symptoms were pyrexia, headache, and neck-rigidity. The C.S.F. on admission contained 630 cells per c.mm. (lymphocytes 70%); on subsequent examinations the cells were nearly all mononuclears. The blood on admission contained 15,000 leucocytes per c.mm. (polynuclears 75%). Glands became palpable for the first time on the thirteenth day. On the sixteenth day the leucocyte-count was 9000 per c.mm. (mononuclears 65%). The Paul-Bunnell reaction was positive on the nineteenth day in 1 : 160, and on the twenty-ninth day in 1 : 640. The C.S.F. still contained an excess of cells four months later.

In this case the initial blood-count showed a polynucleosis in spite of the very high lymphocytosis in the C.S.F., and the glands did not enlarge until later.

NEUROLOGICAL SYMPTOMS

Various types of cranial- and peripheral-nerve palsies may develop in glandular fever, such as ocular paralysis (Fledelius 1935), facial paralysis and optic n (Gsell 1937), and serratus-magnus palsy (Rich 1942, Saksena 1943).

I have personal knowledge of several cases neurological manifestations of various types in glan fever which support those cited above without mate adding to them. On these illustrative cases the follo observations can be made:

(1) There is great variation in the neurological manif tions. The symptoms are most commonly meningeal may be meningo-encephalitic or encephalitic, or the c and peripheral nerves may be involved, and v localisations may develop in sequence.

(2) The neurological symptoms may develop together w or before or after the usual characteristic features of glandu fever.

(3) The common characteristics of glandular fever tend be slight, as is usual in its severer forms. The glandul enlargement is usually mild or may be absent.

(4) *During the period of neurological symptoms*, or at le in the early stages, the blood-count may be normal definite polynuclear leucocytosis may be present. (It long been known that at the onset of the severer types *glandular fever the blood-count may show a high de* polynuclear leucocytosis or may be normal or leucopenic.)

(5) The morphological character of the mononuclear ce present is of importance.

The next question is how these neurological sympto in undoubted cases of glandular fever compare with th recorded in benign lymphocytic meningitis. It can, think, be accepted that changes in the C.S.F. are identi in the two conditions, and that there is no difference the duration and prognosis.

The following account of the symptoms of beni lymphocytic meningitis is summarised from an editori in THE LANCET (1936). The onset is acute, sometim preceded by a sore throat. Severe headache is usual the first symptom and is soon followed by other eviden of meningeal irritation or of increased intracrani pressure; stiffness or pain in the neck, back, abdome or limbs; vomiting, restlessness, and insomnia. Drow ness, delirium, and stupor are rare, and convulsio uncommon except in infants. Gross papillœdem pupillary changes, and cranial-nerve palsies do not oft develop. Early pyramidal signs in the arms, trunk, legs may perhaps be found but are not conspicuo The prognosis is excellent. Recovery is rapid, a patients can leave their beds in the third or fourth we of the illness.

Viets and Warren (1937) have published the only fa case of which I am aware. The patient was a man ag 20 years. The onset began with slight headache, follow by attacks of vomiting. On admission to hospital was mentally clear. There was no paralysis of cran nerves. The neck was definitely stiff. There was paralysis of arms or legs. The C.S.F. was under pressu and contained over 300 cells per c.mm. (lymphocyt 98%). The symptoms temporarily improved, but on th thirteenth day he became restless, and he died durin convulsion next day.

The various points of a neurological examination e.g., the condition of the optic fundi and of the reflexes have not been referred to, but it is justifiable to say th the published work reveals no differences between th two conditions.

From a study of the available publications and fro personal experience I can find no points of differenc between the neurological symptoms of benign lympho cytic meningitis and those of glandular fever, or betwee the changes in the C.S.F. in the two conditions.

DIFFERENTIAL DIAGNOSIS

How, then, can benign lymphocytic meningitis an glandular fever be differentiated? One indication woul obviously be that, in a case with the symptoms of benig lymphocytic meningitis, the special characteristics o and other volatile components are driven off, depends on the type of ore and the cost of transport. In this area the ore is mixed, in the field where it is mined, with coal cobbles and slack and "burnt"—i.e., dehydrated—and the resulting cloud of smoke, containing fluorine compounds, drifts over the countryside. The direction of the prevailing wind in this area is shown by deterioration in the growth of field crops in the immediate vicinity of the smoke. Wheat and barley embryos do not mature, and it is customary for farmers to obtain compensation from the mine-owners, based on the difference between the expected and actual grain yield. At the height of calcining the density of fumes may even make driving on neighbouring roads difficult. In one instance a local practitioner, summoned to an accident in daylight, was unable to see where his patient lay.

Farmer X's home, a small brick house with numerous outbuildings, is situated in the midst of his fields, so that "one fence surrounds them all." In this he differs from the owners of the neighbouring fields near the ironstone burning dumps ("cally heaps"), who live elsewhere. A well on his land supplies Farmer X's house; the water, examined twice, has contained 0·4 and 0·6 p.p.m. of fluorine; the higher figure, obtained in wet weather, suggests the possibility of surface percolation of fluorine or its compounds.

Domestic and Habitual Factors Increasing the Hazard.—The house is poorly constructed, and the windows do not fit. All the family suffer when fumes drift over the farm. Food in the larder is exposed to these fumes and is covered with red dust when the calcined ore is loaded for dispatch. Farmer X's daughter (case 3) complained that she could not clean the glass on the windows facing the fumes. Subsequent examination by an expert of a piece of window glass from the bedroom of Farmer X's mother (case 8, with a high excretion of fluorine) has confirmed that the changes on the surface of the glass can be explained as due to the action of hydrogen fluoride.

Occupational and Economic Factors.—During the past six years, since ironstone burning has been carried on more continuously and nearer to the farm, 7 horses and 11 cows have died; young cattle and sheep have been under weight; the sheep also have been lame and had nasal discharge; and much poultry has been lost. But for the war-time increase in agricultural prices the farm would have been abandoned. Farmer X (case 1) has also been very worried about his own health and that of his family. A young labourer (case 9), who chose agriculture instead of military duty and was "directed" to this farm, says he would really enjoy his work but for stomach pain.

Nutritional Factors.—Family X has experienced no shortage of milk or pork; pieces of home-cured bacon can be seen hanging up in the kitchen. Their vegetables, grown round the farm, are of poor quality. Surface contamination of food with fluorine compounds may explain the raised fluorine levels in these people's urines.

Educational Factors.—Until the recent investigation of cattle fluorosis, the significance of fluorine in this area had not been appreciated. Farmer X was convinced

FARMER X'S HOUSEHOLD

Case no.	Description	Age (yr.)	Occupation	Length of residence at farm (yr.)	Previous residence	Degree of dental fluorosis	Symptoms	Urine analysis* (Dr. H. H. Green), fluorine p.p.m. corrected to sp. gr. 1·015	Remarks	Radiological examination
1	Farmer X	38	Farmer	14	Leics	Moderate	Frequent cough, pain in right shoulder, blurred vision unrelieved by glasses, pain over head	2·9	Youngest child of cases 1 and 2 died at 2 months of bronchitis in April, 1941	Slight arthritis of right acromio-clavicular joint; *no lesion seen in chest*
2	Wife of X	41	Housewife	14	Leics, born Notts	(Edentulous)	Loss of appetite and of weight; recent pneumonia; stiffness of left elbow	2·3	..	Old calcified tuberculous lesion in right upper lung; *no lesion seen in left elbow*
3	Daughter of cases 1 and 2	15	Housework	14	Leics	Moderate	Stiffness in both knees and calves, worse in winter	1·6	Has winged scapulæ and a "Rossetti" neck	No lesions seen in chest or knees
4	Son of cases 1 and 2	13	At school, farmwork in holidays	13	..	Moderate	Left leg aches when he runs	4·2	Sleeps facing fumes; window glass etched	No lesions seen in chest or left leg
5	Son of cases 1 and 2	9	Schoolboy	9	..	Mild	Frequent catarrh and cough	Not examined	Sleeps with case 4	Slightly increased markings in chest
6	Son of cases 1 and 2	3	At home	3	..	Moderate in milk-teeth	Pain in knees, legs, and ankles; two attacks pneumonia; continuous bronchial catarrh	2·0	..	No lesions seen in knees, ankles, or chest
7	Father of case 1	78	Shepherd	14	Leics	(Edentulous)	Bronchial catarrh; pain in stomach	Not examined	Sleeps with case 8	No definite lesions seen in chest
8	Mother of case 1	80	Housewife	14	Leics, born Rutland	(Edentulous)	Pain in back and right knee	4·1	Sleeps in room facing fumes, window glass etched	No change in bones of thoracic cage; bones show some increased markings, particularly basal, compatible with congestive change
9	Directed "worker"	18	Agricultural labourer	1	London, S.E.†	Moderate	Gastric upsets	..	..	No lesion seen in chest

* The "corrected values" here take an average normal sp. gr. as 1·015 for the human subject and facilitate comparision of individuals irrespective of water output. An average fluorine figure for human urine on city dietaries may be taken as anything up to 0·5 p.p.m., so long as the water-supply does not itself exceed this figure When it does, the urine figures tend to approximate to the higher water-values (McClure and Kinser 1944). The domestic water used by this household contained 0·6 p.p.m.

† For fluorine figures in various sources of London's water-supply, see Metropolitan Water Board (1936); Murray and Wilson (1945).

development. Gastric derangement is an early diagnostic symptom, and respiratory embarrassment is not uncommon. More precise information on the degree and effects of exposure is obtained by chemical determination of the range of excretion in the urine and, at a later date, by radiological examination of bone. The severity of fluorotic lesions is influenced by the customary diet and bears a definite relation to the economic status of a community (Pandit et al. 1940). Spinal deformity in later life may result from progressive degeneration of malformations laid down in youth; even where fluorine absorption has been excessive, bone symptoms may not be appreciated for some considerable time (Kemp 1946).

EXAMPLES OF FLUOROSIS RECOGNISED IN THIS COUNTRY

Acute Accidental Effects.—(1) Consumption of an insect powder containing sodium fluoride by a farmer's wife (Bell 1936).

(2) Gastric upset, among Nottingham workgirls, from fluorine introduced into cake with a baking-powder prepared from rock phosphate (*Lancet* 1943).

The interdepartmental committee on food standards of the Ministry of Food have now under consideration maximal limits for the fluorine content of calcium acid phosphate sold for use in food (*Analyst* 1946).

Chronic Absorption.—(1) Fluorosis due to *drinking-water:*

Radiological investigations were carried out on Essex children from Maldon, where mottled enamel in Britain was first recognised (Ainsworth 1933). The domestic water has been shown to contain over 3·5 p.p.m. of fluorine, and severe dental fluorosis has been demonstrated and was associated with developmental disturbances of ossification (Kemp et al. 1942).

(2) Fluorosis as an *industrial disease,* from the known use of fluorine:

(*a*) From *fluor-spar:* Wilkie (1940) recognised osteosclerosis radiologically in two Yorkshire workmen occupied in the manufacture of hydrofluoric acid and of aluminium fluoride. Subsequent analyses showed that their daily urinary output was at least four times that of normal controls.

(*b*) From *cryolite* used as a flux in the manufacture of aluminium: the fluorine output of one aluminium factory was studied by the industrial medical research unit under Dr. Donald Hunter (1946). It found that these works handled some 800 tons of cryolite a year, much of which was lost to the atmosphere and settled in particulate form on the surrounding fields, in which grazing sheep and cows developed fluorosis. Inside the factory skeletal fluorosis was demonstrated in 28 out of 264 furnace-men examined, none of whom complained of disability.

(3) "*Neighbourhood*" *fluorosis:*

(*a*) From a known source of *atmospheric contamination* (cryolite): Boddie (1945) recognised fluorosis in sheep on pastures contaminated by the fumes of an aluminium factory $1^1/_4$ miles distant. Alveolar periostitis not only made it impossible for the sheep to chew their food properly but also led to infection of the sinuses of the skull and to obvious purulent nasal discharge.

In the same part of Inverness-shire we found that the local water-supply had a very low fluorine content (0·2 p.p.m.), but we observed "moderate" dental fluorosis in the milk-teeth of young children whose homes lay within the district contaminated by vapours from the factory chimneys.

Such a condition in the temporary dentition is usually associated with a high maternal intake of fluorine. Children using the same water, whose homes lay outside the affected area, did not show mottled enamel.

(*b*) From the unsuspected evolution of fluorine from a *marine clay* used for brickmaking: agriculturists exposed to the fumes of Bedfordshire brick-works (Wilson 1939) complained of respiratory distress.

Bosworth et al. (1941) and Blakemore (1942) studied the onset and prevention of fluorosis among animals in the same neighbourhood. The origin of the fluorine was traced to the local clay used in the brick-factory, which parted with about a third of its fluorine content (550 p.p.m.) at the higher temperatures, above 900° C, of the kiln. Condensed in the flues to an oily mist by association with volatile products from the organic matter in the clay, fluorine drifted down from the contaminating surrounding pastures to a distance of a mile on the leeward side. Fluorine values up to 90 were shown by hay and grass.

Farm animals differed in susceptibility, lactating being the most vulnerable. Cows had such acute ost trophy that they sometimes knelt to eat. Values for f in urine often exceeded 20 times the normal figure.

Control observations on cattle in the neighbourho south-east Lancashire brick-works using clay depos non-marine origin gave negative results.

On a recent visit to the Bedfordshire area we learn fluorine hazards to grazing animals had been temp met by the "ploughing-up" campaign of the war agricu emergency committee.

(*c*) From *coals* as a possible hazard: Crossley (investigated the amounts of fluorine in British coals types, anthracite and bituminous. He determined by r analysis that their fluorine content ranged from 0–175 p and concluded that coals containing over 85 p.p.m. of flu were potentially harmful in industry.

In beer manufacture with the direct type of *kiln* a fluorine in malting coals passes on to the malt; in present dilute state British beers contain only 0·4–1·0 p of fluorine, but considerably more fluorine is present i "culm" (lees) used as a cattle food.

In coal-mines there is intimate association of the flu containing phosphates with the shales of roof and floor, take part in the formation of dust at the coal-face. I suggested (International Labour Office 1940) that pulm changes took place from the inhalation of dust conta both silica and fluorine.

Fluorine is present in the water from some mines and i domestic supplies of many mining communities (Kemp Wilson 1946). Fluorine in coals increased the hazar fluorosis during the local calcination of ironstone (see be

(*d*) From *ironstone calcination:* Green (1946) iden the cause of lameness and cachexia in some Lincol cattle as an effect of the local burning of ironstone.

The urine of four affected animals contained from times the normal amount of fluorine, urinary values of p.p.m. being encountered.

Fluorine in the bones was much increased, values 10,000 p.p.m. in the ash of ribs to 15,000 p.p.m. in the a femur and vertebræ being shown as compared with 500 p in normal bone ash from cattle in other areas.

Water in the cattle drinking-trough did not contain than 0·5 p.p.m. of fluorine.

The ironstone contained about 1200 p.p.m. of flu which came down to about 300 p.p.m. on calcining with slack in heaps on the fields.

The coal contained over 100 p.p.m. of fluorine and therefore another source of contamination. The drifted on to the surrounding vegetation. Near the calc mounds grass showed very high values, up to 2200 p.p.m. more distant stacks, adjacent to the farmhouse, 68–487 p of fluorine. Members of the farmer's household show raised excretion of fluorine in their urine.

We have studied the ultimate and contributory ca and present manifestations of this particular outb of fluorosis, as it affects the public generally.

FARMER X'S HOMESTEAD

Details of Farmer X's family and associated wo are summarised in the accompanying table.

Environmental Factors.—Ironstone workings in s Lincolnshire lie in an agricultural district of low and wide valleys. Mounds formed by the rocky burden of the mining pits stand out from the cultiv land, which is both arable and pasture. Some farms isolated, but many agricultural workers live near s villages. The ironstone industry is of consider antiquity, but since 1939, owing to war-time requ ments, workings have been extended very considera About 25–30% of iron is obtained from this rock, w compares favourably with many imported samp Mining pits are in the form of long trenches 8–40 ft depth; land has only been levelled for return to agri ture when ore is extracted from near the surface.

Whether the ore is conveyed direct to central b furnaces or first calcined, so that hygroscopic moist

RELAPSING BENIGN TERTIAN MALARIA TREATED WITH PALUDRINE

R. D. C. Johnstone
M.D. Lond., M.R.C.P.

TRIALS with 'Paludrine' in benign tertian (B.T.) malaria were carried out under the direction of the War Office and the malaria committee of the Medical Research Council at Colchester Military Hospital, beginning in July, 1945.

The following three different courses of treatment were used, each being given in strict rotation :

(1) Paludrine 0·05 g. daily for ten days.
(2) Paludrine 0·5 g. daily for ten days.
(3) Quinine gr. 30, pamaquin 0·03 g. daily for ten days.

Patients were carefully selected ; for example, those who had been given any treatment before admission to hospital were excluded. In every case there was a previous history of malaria, the vast majority having been proved by blood slide. Between July, 1945, and March, 1946, 324 cases, 108 of each series, were treated.

Blood slides, thick and thin, were taken when the patients arrived in the ward, and in the event of these showing *Plasmodium vivax*, and provided the cases were in other ways suitable, treatment was begun next morning. Above each bed was hung a specially prepared coloured chart on which the nurse responsible entered and signed for each dose of drug given. Every precaution was therefore taken to guard against possible errors in treatment. Each patient was allotted a serial number, and full particulars were entered on a special form devised by the malaria committee. In view of the difficulty of tracing patients after leaving hospital, these particulars included the patient's unit regiment, home address, and "age and service group." This was well rewarded in the final follow-up.

The drugs were given in divided doses, the paludrine twice a day, the quinine-pamaquin three times daily after food ; none of the paludrine cases showed any digestive symptoms.

Patients were confined to bed until they had been afebrile for forty-eight hours, a temperature of over 99° F being considered pyrexial. After the patients had been allowed out of bed, their activities were in no way restricted ; and, apart from ensuring an adequate fluid intake, no special precautions were taken throughout the stay in hospital.

Blood films were examined on the eighth, ninth, and tenth days of treatment in the first 240 cases ; but, owing to shortage of laboratory staff, this was later discontinued. The results of these investigations showed all except one patient to be negative for asexual parasites. This one patient was being treated on the quinine-pamaquin course, and on the ninth day of treatment scanty B.T. rings were seen. Subsequent follow-up showed that this patient was free from relapse after six months.

Patients were normally discharged from hospital on the day following completion of treatment, when they were given two prepaid postcards for return to me. On these was printed a form asking for details in the event of a relapse. Each patient was also asked, in the event of no relapse, to return the first card after three months and the second after six months. Less than 20% of the patients used the cards for the purpose for which they were intended.

RESULTS OF TREATMENT

Immediate.—There was a rapid response to all forms of treatment, and little difference in results was seen in the three series. The number of days of pyrexia were as follows :

Course	*Average no. of days of pyrexia after start of treatment*
Paludrine (0·05 g.)	1·49
Paludrine (0·5 g.)	1·47
Quinine-pamaquin	0·98

Remote.—Six months after discharge from hospital each patient was sent a standard form asking for information regarding further relapses. If this report indicated a clinical relapse, a second questionnaire, about rigors, periodicity of symptoms, duration, and treatment, was sent. From this information the cases were divided into proved relapses, clinical relapses, and no relapses. As the investigations progressed, an increasing number of patients fell into the doubtful category, owing to many of them being demobilised and therefore no longer entitled to treatment in a military hospital.

The response to follow-up was remarkably good, and many patients replied at the first request. Just over 450 letters were required to trace the 324 cases. Every patient in the series has been followed up, and only one has been excluded from the final analysis (table I). This patient had a further attack of B.T. malaria in Cairo, where it was considered he might have been reinfected.

TABLE I—REMOTE RESULTS OF TREATMENT

Course	No. of cases	Free from relapses	One proved relapse	Two or more proved relapses	Clinical relapse	% relapsed	
						All cases	Proved cases
Paludrine (0·05 g.)	108	62	26	7	13	42·6	30·5
Paludrine (0·5 g.)	107	60	23	2	22	43·9	23·3
Quinine-pamaquin	108	91	9	1	7	15·6	9·2

The standard quinine-pamaquin treatment has been used as a *control* in this investigation. The results obtained here may therefore be compared with previous findings, which show relapse-rates of 10·3% proved cases,[1] 11·3% proved cases, and 16·5% total relapses.[2] There is therefore no significant difference in the quinine-pamaquin results, and those obtained with paludrine may be reasonably concluded to be equally accurate.

FACTORS POSSIBLY INFLUENCING RELAPSE-RATE

Captivity.—Of the total series, 89 cases (27·4%) were patients who had been prisoners-of-war in the Far East. Since the relapse-rate of these might be expected to differ from the normal cases, owing to most of them having had very inadequate treatment and very frequent attacks while prisoners, they have been analysed separately (table II). The relapse-rate is higher than in the other cases ; but, since the distribution of prisoner-of-war cases shows almost equal division between the total paludrine and quinine-pamaquin series, it is justifiable

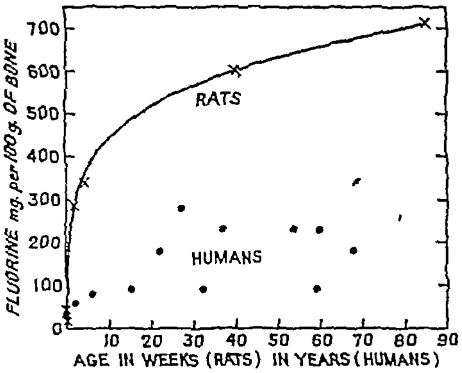
that both his family and his stock suffered from the ironstone fumes and had sought all possible local diagnostic aid since 1940, but it was only the identification in 1946 of the fluorosis in cattle which provided the clue to the lesser symptoms in the human subjects.

Control Observations.—At a farm adjacent to ironstone pits from which the ore was sent direct to blast furnaces without local calcining there was no sign or history of illness in either the members of the household or in their farm stock. Their domestic water contained 0·35 p.p.m. of fluorine in wet weather. Fluorine in small quantity is to be expected in the local springs deriving their water from the ironstone beds; and inspection of adolescents in five neighbouring villages showed teeth with a "very mild" degree of mottled enamel. At the blast furnaces dealing with this ore no history of *clinical disability* attributable to fluorine was obtained from workmen employed for over fifteen years.



Increase in fluorine content of bones of rats fed 5–7·5 mg. of sodium fluoride a day, and fluorine content of fat-free dried rib bones of persons of different ages resident in London for most of their lives.

DISCUSSION

The absorption of the products of fluorine combustion by the affected cattle consuming heavily contaminated hay and grass was obviously more intense than by Farmer X's family who presumably consumed only small quantities of contaminated foods. The human clinical symptoms are, however, in line with those recorded in chronic endemic fluorosis among people using waters with a raised fluorine content: Argentine (Roholm 1937); China (Lyth 1946); South India (Shortt et al. 1937); North India (Wilson 1939, Khan and Wig 1945); South Africa (Ockerse 1941); United States (Linsman and McMurray 1943).

Judging from the experience of these countries, it was unlikely that skeletal changes resulting from the absorption of fluorine would be appreciable radiologically within the period, about six years, in which Farmer X's household has been exposed to the effects of the intensive ironstone calcination; there is, however, abundant human evidence from other parts of the world that fluorine intake above tolerance levels over a sufficient period (as shown by raised excretion of fluorine) can lead to cumulative absorption and prove harmful to the human organism.

That fluorine must be regarded as a cumulative poison is well established by chemical and experimental observations. The bones of Danish cryolite factory workers contained about ten times that of average persons, the highest fluorine content being found in the worker with longest exposure; osteosclerosis resulted from the daily retention of about 25 mg. of fluorine (Roholm 1937, Brun et al. 1941). Animals given small amounts of sodium fluoride in the diet showed an increasing fluorine content of their bones (Glock et al. 1941). The accompanying figure shows the increase in fluorine content of the bones of rats fed 7–10 mg. of fluorine a day. A series of estimations of the fluorine content of the fat-free dried rib bones of persons of different ages resident in London for most of their lives is given in the same figure; these also show, on the whole, an increase in fluorine content with age.

Etching of window glass in houses facing the fumes should lead to inquiry for possible *clinical* of fluorine absorption. Recently fluorosis was rec in cattle grazing in the neighbourhood of a Shrop colour and enamel factory. Fluorine values in the of the affected cattle ranged from 19–37 p.p.m. W in the animals' drinking-trough did not contain more t 0·6 p.p.m. of fluorine, but there was severe contaminat of pasture, samples of air-dried material show 776–115 p.p.m. of fluorine at distances of 30–600 ya from the factory. During the winter these cattle h been fed on hay cut from another farm, and their expos to fluorine was mainly at grass in summer; their skele lesions were not so pronounced as those of cattle near t brick-works and ironstone dumps (see above); but af three or four years' exposure their molar teeth were w down to the gums, and the permanent incisors w distorted and misshapen. In the windows of an adjace farmhouse etching of the glass by the fumes was reporte it was sufficiently severe to necessitate window-gl replacement by the family every two or three yea Human fluorine hazards in this neighbourhood had yet received attention.

SUMMARY

Fluorine hazards, actual or potential, in this count have been described.

An example has been studied of some importa secondary consequences for dwellers in the neighbourho of certain industrial undertakings.

It is a practical proposition to extract fluorine fro fumes before allowing them to pass into the atmosphe This is already the practice of some firms. In the examp studied the substitution of closed kilns in the burni of ironstone would make the amount of fluorine prese in the ore and coal immaterial from the public heal point of view, but methods for such fluorine control a at present too rarely applied in this country, becau fluorine hazards are not sufficiently appreciated.

An investigation to ascertain the nature and location all industrial processes creating a possible fluorine haza seems to be desirable.

The need for a better intelligence service and coör nating mechanism to ensure collaboration betwe Government departments, industries, local authoriti and research workers is also apparent.

We wish to thank Dr. H. H. Green, of the Ministry Agriculture's veterinary laboratory, Weybridge, for supplyi much information and for his help in many different way our colleague, Dr. F. H. Kemp, for reporting on the rad logical examinations of Farmer X's household, to whom acc was very kindly given by their family doctor and the coun health authorities concerned; Mr. C. N. Bromehead, of t geological survey, for providing data throughout this inquir and Mr. A. C. Pilkington for his examination of glass. W also wish to thank the Medical Research Council for expenses grant.

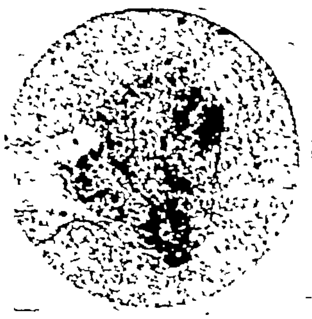

Fig. 1—Anterior sulcus of cervical cord showing an inflammatory focus of lymphocytes and erythrocytes. (Low power, Mann's stain.)

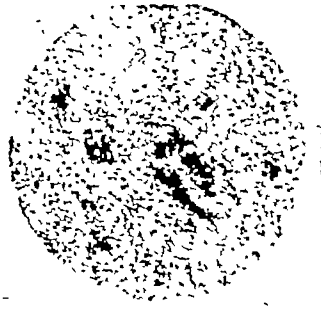

Fig. 2—Left anterior horn of cervical cord showing patches of hæmorrhage. (Low power, Mann's stain.)

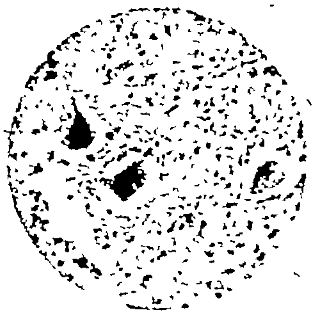

Fig. 3—Degenerating nerve-cells showing destruction of their nuclei—left anterior horn of cervical cord. (Mann's stain.)

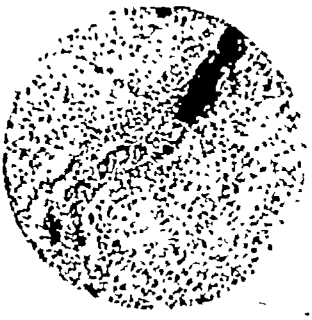

Fig. 4—Left anterior horn of cervical cord showing perivascular cuffing with lymphocytes. (High power, Mann's stain.)

Lumbar puncture was achieved under light 'Pentothal' anæsthesia. Pressure was normal, and there was no spinal block. The fluid showed a slight haze, made more evident on shaking the test-tube, but it cleared on standing. The cell count was 120 per c.mm., with a preponderance of lymphocytes. The fluid was centrifuged, and a smear stained by Gram's method showed no organisms. The patient recovered consciousness but died in his sleep six hours after the lumbar puncture.

Necropsy.—No naked-eye changes were observed in the brain, spinal cord, or meninges, and nothing of note was found in the other organs.

The brain was removed and put into formalin without opening. Sections were taken from the cerebral cortex, the cornu Ammonis, and the cervical cord. They were stained with hæmatoxylin and eosin and by the method of Mann for negri bodies. They were examined by Prof. Vittorio Cilli at the Vaccine Institute, Asmara, a summary of whose report follows:—

"No negri bodies were found in the cornu Ammonis. Apart from a little vascular congestion the brain appears normal. The pia mater in the anterior sulcus of the cervical cord is acutely congested and infiltrated with lymphocytes and erythrocytes (fig. 1). This process extends into the periphery of the cord along the pial vessels.

"The grey matter of the left anterior horn of the cervical cord shows a large hæmorrhagic area speckled with foci of lymphocytes (fig. 2). This area extends into the corresponding posterior horn and into the adjoining right anterior horn. Some of the ganglion cells in this area are degenerate or destroyed (fig. 3). The changes vary from simple wrinkling of the nuclear membrane to karyorrhexis and karyolysis. The cells most affected are those of the left anterior horns. The cytoplasm of the affected cells shows corresponding regressive changes, the tigroid substance in many cells being reduced or absent. No intranuclear inclusion bodies were seen.

"There is infiltration with lymphocytes and erythrocytes in the lateral columns of the left side of the cervical cord. In other parts of the white matter perivascular cuffing with lymphocytes (fig. 4) and erythrocytes was seen.

"The picture is one of acute hæmorrhagic lymphocytic myelitis with spinal leptomeningitis."

Some brain substance was removed from the centre of the brain twelve hours after necropsy and emulsified with normal saline. Two rabbits were each injected subdurally with 0·15 c.cm. of the brain emulsion obtained. Both were reported to be alive and well two months later.

DISCUSSION

At different stages of the illness described, diagnoses of meningitis, acute anterior poliomyelitis, and rabies were considered. These possibilities were discarded in turn, and a diagnosis was made of myelitis due to antirabic vaccine, terminating in a bulbar palsy.

Paralyses from this cause are not uncommonly reported, but in most cases the paralysis is transient and recovery the rule.[1] The explanations put forward fall into two main groups, either a virus or a toxin being held responsible. In cases where living attenuated rabies vaccine has been used—the group in which paralyses most often ensue—the rabies virus in the vaccine is naturally incriminated. In other cases the rabies virus inoculated by the rabid animal in its bite may cause the paralysis, the full picture of rabies being masked by the protective action of the vaccine.[1] Other and more speculative viruses have also been postulated—for instance, a neurotropic virus in the animal brain substance used in making the vaccine, and a dormant potentially neurotropic virus already present in the tissues of the host.

The toxin theory supposes that the heterologous brain substance in the vaccine is toxic to the central nervous system of the host. This may be a direct cytotoxic action or anaphylactic, the patient becoming sensitised by repeated injections.

In the present case it is impossible to say which of these factors was operating. The lack of inclusion bodies in the patient's brain or spinal cord and the negative result of the rabbit inoculations might be held against a virus but do not exclude it. The time of onset of the symptoms, four days after the last injection, does not suggest anaphylaxis.

No other accidents have been reported following the use of this batch of vaccine, and subsequent laboratory investigation of the vaccine for toxicity proved negative. It appears therefore that the patient exhibited an abnormal sensitivity to some chemical ingredient of the vaccine.

I am much indebted to Prof. Vittorio Cilli, director of the Vaccine Institute, Asmara, for doing all the pathological work in this case and for taking the photomicrographs. At his request the sections were also examined by Dr. R. Kirk at the Stack Laboratories, Khartoum, who concurred in the findings. Thanks are also expressed to Colonel W. H. Greany, S.M.S., commanding no. 2 S.D.F. base hospital, for permission to publish this case.

[1] Levaditi, C., Lépine, P. Les ultravirus des maladies humaines, Paris, 1938.

"The real division of hospitals at the present time is not between 'voluntary' and 'municipal.' It is between hospitals for the urgent and short-duration patients and hospitals for long-lasting and recurrent illness. . . . From their first sitting the new regional boards should face their responsibilities as a whole. The total hospital demands of the community must be considered together. . . . This is the moment for a change of policy. The needs of invalid children and of the tuberculous are already being met by long-stay hospitals and sanatoria. There remains the immediate task of improvising for the adult and elderly something comparable. . . . A vast programme of construction will be necessary. . . . What is needed more than anything material, however, is an awakening of the whole community to the existence in their midst of a state of affairs often tragic in its melancholy and suffering."
—Sir Ernest Rock Carling in the *Times* (Nov. 25).

TABLE II—RELAPSE-RATE AMONG PRISONERS-OF-WAR AND OTHERS

Course	Total	Free from relapse	Proved re-lapses	Clinical re-lapses	% relapsed	
					All cases	Proved cases
Far East prisoners-of-war						
Paludrine (0·05 g.)	25	12	8	5	52 0	32·0
Paludrine (0·5 g.)	35	13	8	14	62·8	22·8
Quinine-pamaquin	29	20	5	4	31·0	17·2
Other cases						
Paludrine (0·05 g.)	83	50	25	8	39·7	30·1
Paludrine (0·5 g.)	72	47	17	8	34·7	23·6
Quinine-pamaquin	79	71	5	3	10·1	6·3

to include them in the totals provided it is realised that the total relapse-rate is thereby increased.

Return to England.—As relapses are more definite and more likely during the first few months after return to England, the time interval between arrival in U.K. and admission to hospital has been compared in the different series:

Course	*Average months in U.K.*	*Maximum*
Paludrine (0·05 g.)	3·26	11 months
Paludrine (0·5 g.)	3·31	1 year
Quinine-pamaquin	3·13	9 months

There is no bias in favour of any of the three treatments.

Probable Area of Infection.—Since different strains of *P. vivax* may possibly cause relapses at different intervals, the probable area of infection has been compared:

Course	*India-Burma*	*Mediterranean area*	*Far East*	*Others*
Paludrine (average for both courses)	65·5	10·5	30	1·5
Quinine-pamaquin	64	14	29	1

The probable area of infection does not seem to have influenced the relapse-rate in the different series.

INTERVALS BETWEEN RELAPSES

The interval between treatment and proved relapse has been assessed as follows:

Course	*Average no. of days between treatment and proved relapse*
Paludrine (0·05 g.)	65·1
Paludrine (0·5 g.)	53·0
Quinine-pamaquin	43·7

These findings are open to much criticism, as there is no doubt that some patients took occasional and inadequate doses of mepacrine after leaving hospital, though they were advised not to do so. As a result, it is probable that the relapse period in these cases was prolonged.

SUMMARY

Paludrine has been used in the treatment of 216 cases of relapsing B.T. malaria, while 108 control cases have received the standard quinine-pamaquin treatment.

A six-month follow-up has been obtained in all these cases, and the results show a relapse-rate associated with both dosages of paludrine over double that associated with quinine-pamaquin.

No appreciable difference has been noted between the results of small or large doses of paludrine.

This investigation does not include all the relapses, because the period does not cover sufficient time after treatment, it being generally agreed that a second but small peak of relapses is to be expected in the 250–300 day period. Thus one case treated on paludrine (0·5 g.) is here given as "no relapse," having had his first rel 240 days after leaving hospital.

Quinine-pamaquin treatment probably causes temperature to fall to normal slightly quicker than d paludrine.

There is a suggestion that paludrine given in a ten- course causes a longer period of freedom from rel than does quinine-pamaquin, in spite of the high rela rate.

Paludrine given in a ten-day course is effective treating acute attacks of B.T. malaria but in no compares with the standard quinine-pamaquin treatm in controlling further relapses.

I wish to thank Major-General Sir Alexander Bigg consulting physician to the Army, for permission to pub this paper; and many members of the staff of the Colche Military Hospital, especially the nursing sisters and V.A nurses, for their help. I am also indebted to Imperial Chem (Pharmaceuticals) Ltd. for supplies of paludrine.

MYELITIS AFTER ANTIRABIC VACCIN

REPORT OF A FATAL CASE

L. J. BUSSELL
B.M. Oxfd
LATE MAJOR R.A.M.C.

THE pathogenesis of paralyses following treatment w antirabic vaccine is not yet understood. In the c reported here a necropsy was done.

CASE-RECORD

Clinical.—A Sudanese soldier, aged 25, was bitten on left hand and right ankle by a stray dog on Sept. 3, 19 It is not known whether the dog was rabid or not.

Treatment with antirabic vaccine was started immediat A killed carbolised vaccine was used, made from shee brain according to the method of Semple, a 2% emuls being used. Injections were given subcutaneously the abdominal wall in daily doses of 5 c.cm. ca Between Sept. 3 and Sept. 10 seven daily injections w given.

The patient then defaulted and next came under med care on Oct. 31, when he said that the dog was mad, and it decided to give him a further complete course of antira vaccine. Between Oct. 31 and Nov. 14 he was given thirt daily injections as before. Treatment was then stopp On Nov. 18, four days after his last injection, he complai of pain and twitching in his left upper arm and should He was immediately sent into hospital.

On examination there was fibrillary twitching in the mus of his left upper arm and shoulder girdle. Temperature 102° F, and a blood count showed white cells 9600 (po morphs 45%, lymphocytes 44%, mononuclears 9%, eosi phils 2%). His condition remained unchanged u Nov. 20, when it was found that he could not dorsif his left wrist.

On Nov. 21 neck rigidity and head-retraction develop and there was complete flaccid paralysis of his left a Kernig's sign was positive. Temperature 99 2° F, pul rate 140 per minute, respirations 40 per minute. Noth abnormal found in chest and abdomen. The white-cell count 6400 per c.mm. (polymorphs 52%, lymphocytes 42%, mo nuclears 4%, eosinophils 2%). Lumbar puncture attempted but failed owing to the difficulty in flexing back.

On Nov. 22, the day of his death, he presented a pict of acute distress. Temperature 100° F, pulse-rate 130 minute, respirations 45 per minute. Head-retraction prese The fibrillary twitching had ceased in his left paralysed a but was seen in his right arm and in the chest and abdomi muscles of both sides. He had violent uncontrollable spas of the occipitofrontalis muscle and the muscles of the rig upper lip, and had repeated attacks of retching. profuse mucoid discharge came from his mouth a nose. His mental processes were unimpaired. He spo intelligently and complained of pain in the left clavicu region but could not articulate properly and had difficul in swallowing.

days, and subcultures, together with those made from the incubator series, were tested for penicillin production. The results are shown in table II. Differences in yield among the four sets are not significant by the method of assay used. Therefore the treatment did not succeed in producing a strain of 1978B giving a much higher yield of penicillin than the original strain.

COLCHICINE TREATMENT AND SPORE SIZE

Since polyploidy has often been found to be associated with an increase in size of the cells and especially of the haploid pollen grains, it was thought that spore size might be a useful criterion in testing for polyploidy, since the spores of penicillium are uninucleate. Moreover, large-spored strains have been produced by camphor treatment (Sansome 1946). Spore size was examined by mounting spores in physiological saline and a detergent and by making camera-lucida drawings at a magnification of about 1100. The spores of all strains sent by Gordon and McKechnie were found to be of the same average size. The average spore length for 10 spores was found to be as follows: "2n"=3·0 μ, "4n"=2·9 μ, "8n"=3·1 μ, "16n"=3·0 μ.

It was thought that, if polyploid nuclei were formed in the treated samples, these might well become overgrown by haploid nuclei on mass subculture. Dilution plates were therefore made of spores formed on the original treated cultures. The refrigerator series did not form spores in the refrigerator; so after being at 4° C for three weeks they were put into the laboratory at 55° to 60° F until spores were formed.

TABLE II—PENICILLIN PRODUCTION IN STRAINS OF 1978B SUBJECTED TO COLCHICINE TREATMENT AT 4° C AND 24° C AND IN CONTROLS

Strain	Day						Av. of 3 highest consecutive days
	7th	8th	9th	10th	11th	12th	
1249 B21	38	42	53	65	62	66	64
1978B Control at 4° C ..	53	45	59	47	37	44	48
Colch. at 4° C ..	31	45	50	53	55	61	56
Control at 24° C ..	53	49	63	52	45	65	54
Colch. at 24° C ..	48	59	70	62	54	66	64

After plating, single colonies were examined for spore size. Fifty colonies from the colchicine series in the incubator were examined, and all were found to have spores of the same average size as the control—i.e., a length of about 3·3 μ.

There is no evidence therefore that colchicine can induce polyploidy in *P. notatum* at temperatures of 24° C or 4° C. This is in accordance with the results of other workers.

SUMMARY

Treatment of a high-yielding strain of *P. notatum* (N.R.R.L. 1978B) with colchicine at a normal incubator temperature of 24° C and at a low temperature of 4° C did not significantly affect the yield of penicillin given by the strains.

An examination of spore size in fifty colonies from colchicine-treated cultures did not show any with spores of an increased size, such as might be expected to result from polyploids.

Colchicine is therefore believed to be ineffective in inducing polyploidy in *P. notatum.*

Preliminary Communication

INDUCTION OF GLANDULAR CARCINOMAS OF THE PROSTATE IN THE MOUSE

The empirical treatment of human prostatic carcinoma by the administration of œstrogens, or by castration, has been found to offer such promise of amelioration in recent years that there is clearly a need for an experimental investigation of the reactions of transplantable prostatic tumours in animals to hormonal and other factors. If it were possible to obtain a prostatic tumour which grows at a more or less constant rate, which is readily transplantable, and at the same time retains the structural characteristics of a glandular carcinoma, much might be done in testing various synthetic œstrogens and related compounds as possible growth inhibitors, as well as in investigating the more fundamental problem of the factors influencing carcinogenesis in the prostate gland.

By repeated examination of serial biopsy specimens of prostatic carcinoma in man, Fergusson[1] has shown that the administration of œstrogens causes regression of the neoplasm in nearly all cases, but in some the response to treatment is variable. He has emphasised the need for confirmatory observations on prostatic cancer in animals.

Attempts have been made, therefore, to induce transplantable prostatic tumours in rodents by using the carcinogen methylcholanthrene. The present paper is confined to a description of the technique, which is similar in essentials to that used by Rous and Smith,[2] and later confirmed by Greene[3]; but with one important difference—namely, that in our hands the technique has been successfully adapted to produce transplantable tumours from adult, not embryonic, tissues. We believe this to be the first instance of the induction of a series of transplantable tumours arising from adult tissue growing as homologous subcutaneous grafts. A brief description of the prostatic tumours which have been induced in mice, and which are being maintained by repeated transplantation, is included.

TECHNIQUE

The method of tumour induction consists essentially in isolating a sheet or mass of adult tissue, in this case prostatic epithelium, with a minimum of underlying stroma, which is wrapped round a few crystals of the pure carcinogen, and the whole is then transplanted under the skin of a host animal of the same inbred strain.

The epithelium from either the anterior or dorsal lobes of the prostate of six-month-old mice (Strong A inbred strain) was cut into small strips of approximately equal sizes, using a dissecting microscope. Some crystals of 20-methylcholanthrene were placed in contact with the epithelium, which was rolled up and inserted into a Bashford transplanting needle. The grafts were transplanted into male mice of the same inbred strain, care being taken to maintain the carcinogen in contact with the prostatic epithelium and shielded from contact with the subcutaneous tissues of the host.

In 10½ weeks small primary tumours could be identified growing at a fairly uniform rate. It was found possible in a later series of experiments to make as many as three subcutaneous primary grafts on each side of the belly of a single host, and thus to induce a series of individual tumours growing under the same hormonal conditions.

RESULTS

In the first series of experiments fourteen Strong A mice received subcutaneous grafts of prostatic epithelium impregnated with the carcinogen. Twelve of these primary prostatic grafts formed tumours which proved

COLCHICINE INEFFECTIVE IN INDUCING POLYPLOIDY IN PENICILLIUM NOTATUM

E. R. Sansome M.Sc. Durh.

L. Bannan B.Sc. Lond., A.R.C.S.

From the Department of Cryptogamic Botany, Manchester University, and the Biological Laboratories of Imperial Chemical Industries Ltd., Manchester

Gordon and McKechnie (1945) reported the production of strains of penicillium giving successively increased yields of penicillin after successive treatment with 0·2% colchicine under conditions which they described. They attributed the increased yield of penicillin to polyploidy, assuming that the untreated form was diploid; but they did not count its chromosomes, and it is most probably haploid. The first selection, which they found to give about twice as high a yield as the parent strain, they assumed to be tetraploid. The "tetraploid" was again subjected to colchicine treatment, and a new selection assumed to be "octoploid" was made. Similarly, a further treatment of the supposed "octoploid" gave a new selection assumed to be "sixteenploid."

By the courtesy of Dr. W. W. Gordon, who sent cultures of the strains to our colleague Dr. P. H. Gregory, we have been able to repeat the penicillin-production tests under our conditions. The strains were tested by the surface-culture method, and a culture of the commercial strain N.R.R.L. 1249 B21 was tested at the same time. The medium, a modification of that of Moyer and Coghill (1946), was made up as follows:

Lactose	2%
Dextrose	2%
Sodium nitrate ..	0·3%
Corn steep liquor ..	10%
Phenyl acetic acid ..	0·05%
Water; pH adjusted to 5·6 with sodium hydroxide.	

The results of the tests are given in table I. It is clear that none of the strains approaches the yield of 1249 B21; nor did we find the correlation between yield and strain reported by Gordon and McKechnie. In the first test the "4n" strain possibly gave a higher yield than the "2n," and in the second test the "8n" strain possibly gave a higher yield than the untreated strain. The "16n" strain was low in all our tests. However, none of these differences is very striking. The discrepancy between our results and Gordon and McKechnie's may be due to chance. Penicillin yield is a very variable quantity, and the correlation obtained by Gordon and McKechnie between yield and treatment of strain may have been due to chance and may not be reproducible. Alternatively, since penicillium is an unstable fungus, the cultures finally tested by us may have been different in composition from the original cultures tested. Also, there remains the possibility that the treatment has a stimulatory effect which is more or less temporary.

The original results of Gordon and McKechnie seemed to indicate that higher-yielding strains had been obtained, probably by selection from an original mixture of strains; they did not indicate that these strains were polyploid. On the contrary, in view of the work of Richards (1938), Satina (reported by Blakeslee 1939), and others, in which efforts to induce chromosome doubling in fungi with colchicine were unsuccessful, we thought it unlikely that the strains obtained by Gordon and McKechnie were polyploids. A doubling in the yield of a product does not usually accompany the doubling of the chromosome number. *Very often* polyploidy has no effect on the yield of a particular substance. Sometimes it leads to an increase, but not to the extent of 100%.

It seems improbable, therefore, that Gordon and McKechnie's results are due *to* polyploidy. There remain three possibilities.

(1) The improved strains may have been selected by char

(2) The influence of colchicine or cold or both may b led to a selection of the high-yielding strains. It is a comm practice to store cultures in a refrigerator, and so far strains with increased yields have been reported to result fr this treatment. However, in Gordon and McKechni experiment, spores were allowed to germinate and grow in refrigerator, a procedure which might lead to results obtained by storing mature cultures in a refrigerator.

(3) Colchicine or cold or both might have some stimolati effect, possibly of the nature of a "dauermodifikatio leading to an increased yield of penicillin for some time af the treatment.

In view of these possibilities it was decided to rep Gordon and McKechnie's experiments on a high-yieldi strain, using controls for the colchicine and temper ture effects. At the same time efforts were made determine whether or not polyploids were produced as result of the colchicine treatment.

EXPERIMENTAL

The medium used was the modified Czapek-D medium used by Gordon and McKechnie. It was ma up in double strength as follows:

Sodium nitrate	3·0 g.
Magnesium sulphate, $7H_2O$	0·25 g.
Zinc sulphate, $7H_2O$ ..	0·02 g.
Potassium phosphate ..	0·5 g.
Lactose	30·0 g.
Corn steep liquor	80·0 ml. made up to 0·5 litre with tap water.

The pH was adjusted to 5 with 10*N* NaOH.

For the controls the medium was brought to norm strength by the addition of 1 part medium to 1 pa distilled water. For the colchicine samples 1 part of th medium was added to 1 part of 0·4% colchicine in distille water, bringing the strength to 0·2% colchicine. Tube containing absorbent cotton-wool were prepared an sterilised. To each tube was added 1 ml. of spor suspension containing $2{\cdot}9\times10^8$ spores of the strai N.R.R.L. 1978B. The spore suspension was prepared from a seven-day culture on glycerol-molasses-peptone-agar To four tubes 7·5 ml. of the medium was added, and t four other tubes 7·5 ml. of medium and colchicine. Tw control tubes and two tubes with colchicine were place in the incubator at about 24° C, and a similar set in refrigerator at about 4° C.

After four days the incubator cultures showed consider able growth and spore formation. Subcultures were mad on Saboraud's *agar*. An examination of the spore showed no difference in variability of spore size betwee the control and colchicine-treated samples. The sample in the refrigerator showed no obvious growth after fou days. There was a little thin growth after fourteen

Medical Societies

LIVERPOOL MEDICAL INSTITUTION

In his inaugural address at the opening of the 110th session, Dr. G. F. **Rawdon Smith**, the president, traced the history of anæsthesia from the day that Adam's rib was removed. At first psychical methods, such as hypnotism, magnetism, and mesmerism, held the field. There were also primitive oral anodynes; and physical devices, variously attributed to the Egyptians, Assyrians, Greeks, and Romans, were introduced and persisted into medieval times. The first mention of inhalation anæsthesia is to be found in Pliny, though some claim that it originated in China. Continuing the record down to the present day, Dr. Rawdon Smith emphasised the improvements during his lifetime, and suggested that the present tendency was to attach overmuch importance to anæsthesia compared with surgery.

At a meeting of the institution on Nov. 7, with Mr. J. B. **Oldham**, vice-president, in the chair, a discussion on the late results of

Partial Gastrectomy for Peptic Ulcer

was opened by Mr. A. **Kirk Wilson**, who described a personal and consecutive series of 148 patients who had undergone partial gastrectomy for simple peptic ulceration between 1934 and 1939. Of these, 104 had gastric, 40 duodenal, and 4 jejunal ulceration. Of the patients with a jejunal ulcer, 3 had a gastrocolic fistula, and in 4 of the patients with a gastric ulcer a gastrojejunostomy had first to be undone. Analysis of the patients by age-groups showed that over 50% of the patients with duodenal ulcers were under forty years of age, while 65% of those with gastric ulcers were over forty. In the same period, 117 cases of carcinoma of the stomach were explored, and among these a partial or total gastrectomy was done 48 times.

Before deciding on operation for a high gastric ulcer, the size of the crater, the degree of penetration and fixation, and the response to medical treatment must first be considered. Ulcers of the pyloric antrum and canal were operated on fairly early because of their tendency to malignant metaplasia. With duodenal ulcers the main indications for operation were repeated perforation and recurrence of symptoms after several courses of intensive medical treatment in hospital.

The Polya-Moynihan operation was done for 44 patients, the Hofmeister operation for 45, and the "physiological" for 59. The over-all mortality was 8%; in exactly half of these deaths, necropsy showed that the cause of death was pneumonia and that healing had occurred without infection in the peritoneal cavity. One pulmonary embolus was recorded, and in 3 cases, where permission for necropsy was unobtainable, a leak from the duodenal stump was suspected.

In more recent series the mortality and morbidity had been much reduced by: (1) more intensive preoperative preparation, to correct minor degrees of anæmia and hypoproteinæmia, and (2) improved anæsthesia. With *d*-tubocurarine the relaxation compared very favourably with that produced by a perfect spinal anæsthetic, and chest complications had not caused any anxiety.

Dr. **Robert Kemp** said it must be remembered that the surgeon operated only on medical failures, and that the physician saw only the bad results of surgery. This paradoxical situation took no account of the good results of both methods. The physician had three duties to his patient in regard to surgery: he must have clear-cut indications in his own mind; he must know the risks and drawbacks of operation; and he must follow up the late results of his advice. With most complicated ulcers and with many gastric ulcers the indications for partial gastrectomy were clear. But with duodenal ulcers each case must be considered individually; and the decision as to when the lesion was beyond permanent help from medical treatment should not be delayed. Apart from the immediate postoperative risks, there were those of later stomal ulcer and, it seemed, an increased liability to pulmonary tuberculosis. After operation the patient might also be handicapped by anæmia, small stomach, dumping, lassitude, malnutrition, gastritis in the stump, and the need for further dieting. Of the 148 patients on whom Mr. Kirk Wilson had performed partial gastrectomy 108 had been followed up; of these, 71 were still alive. No less than 55% of these 71 were in excellent health, doing full work and taking a full diet, with no significant symptoms. In another 28% the patients were in good health and capable of full work, but needed a modified diet. In the remaining 17% the result was only fair; despite dieting these patients still had some symptoms and lost some time from work. In every patient seen the condition was better than before operation. There had been a dramatic change from the miserable life of the man with an intractable ulcer to that of the fit active man without pain and full of gratitude to the surgeon even so long after the operation. The results in duodenal ulcer cases were particularly good. Nevertheless, it was still the physician's duty to keep his patient on a régime strict enough to obviate the need for surgery. If he failed in this the operation should be done under optimum conditions, with full preparation and convalescence in the medical wards. The best permanent results would be obtained by giving patients a simple postoperative régime to follow indefinitely, and by seeing them from time to time to ensure that they did so.

Mr. G. C. E. **Simpson** still felt that there were many cases where gastroenterostomy with ligature of the pylorus was the operation of choice. Before 1939 he would have said first choice, but since deprivation of fats now often prevented satisfactory dieting, he made it the exception. Towards the end of 1942 peptic ulcer had increased in frequency, and he had begun to meet numerous patients with gastrojejunal ulceration, often with colic involvement; in several the gastroenterostomy had been done as long as twenty years before, and they had been able to dispense with dieting. But in 1944 their number had again diminished; the change in the flour might possibly have had an influence. For many years all cases of peptic disorder had been seen on a joint ward round with a physician, and referred afterwards to a dietetic clinic.

Mr. **Cosbie Ross** said that in 160 consecutive gastrectomies 8 patients had died as a result of the operation, making a mortality-rate of 5%. Of these 8 deaths, 3 had been from myocardial failure, 3 from lobar pneumonia, and 1 from a pulmonary embolus; and 1 patient had died during the operation. A further 3 patients had died later, 1 from carcinoma of the œsophagus, 1 from carcinoma of the stomach sac, and the third from a perforated stomal ulcer. This last case was interesting since the ulcer had occurred a year after gastrectomy, previous to which there had been two perforations. With these persistent perforations it might be advisable to prevent further trouble by carrying out an almost complete gastrectomy. Of the patients followed up, 55 had been interviewed and examined, 22 having had the operation for a duodenal ulcer and the remaining 33 for a gastric ulcer. It was a sobering thought that over 75% had had symptoms for over five years and that many of these cases had been in and out of hospital for medical treatment.

Of these 55, not one expressed dissatisfaction with the result of the operation; in fact, 47 were extremely grateful. Of the remaining 8, 2 were ill from other conditions, 1 having advanced phthisis and the second syringomyelia. The other 6, though stating that they were much improved, admitted to mild dyspeptic symptoms, such as heartburn, inability to eat greasy foods, occasional vomiting bouts, or discomfort after heavy meals. None complained of even moderate pain. Except the 2 patients ill from other causes, all were working regularly, though some had changed from their normal occupation to some less arduous work. In this connexion it was interesting that 11 out of the 55 complained of a diminution of strength and energy. The short afferent loop was important in making the anastomosis. Recent experiments had shown that the daily intramuscular injection of 30 mg. of histamine-base in beeswax in laboratory animals caused a torrent of acid secretion, which broke down the capacity of tissue in contact with the acid to defend itself. In a series of gastrectomised dogs the histamine-beeswax technique always produced a stomal ulcer when a long afferent loop was used, and never when a short loop was devised.

to be malignant, and many transplants from these are, at the time of writing, in their eighth generation. Of the remaining implants which did not develop into tumours one was found at necropsy not to have become vascularised. Eleven of these tumours on histological examination proved to be glandular-celled carcinomata and one was a squamous-celled carcinoma.

A study was also made of the early phases of carcinogenesis within primary grafts of prostatic tissue. In this connexion it should be stressed that the technique used, whereby crystals of the carcinogen were placed in direct contact with the living tissue, without using a solvent such as lard or oil, resulted in no foreign-body reaction, and left no residue or necrosis within the graft which might mask or conceal the actual areas where neoplastic changes first arise. In serial sections of primary grafts it was found possible to relate individual invading masses of malignant cells by continuity with the particular alveolus lined with hyperplastic epithelium from which they had arisen. Well-marked hyperplasia was always found to precede the appearance of malignant change.

All types of tumours which developed in the grafts belonging to the first series of experiments were glandular-celled carcinomata (figs. 1 and 2), with the exception of one which was a scirrhous carcinoma.

Secretory activity was a prominent feature of the primary grafts and was surprisingly abundant even in some of the transplanted tumours of the eighth passage. It was common to find prostatic fluid encysted within distended alveoli; the secretory activity seems to depend, as might be expected, on successful vascularisation of the grafts.

DISCUSSION

Previous attempts to induce by experimental means a transplantable prostatic carcinoma in laboratory animals have been only partially successful; thus Moore and Melchionna [4] injected benzpyrene into the prostates of rats and obtained squamous-celled carcinomata and sarcomata, but they gave no information as to whether transplantation of these tumours was successful. Dunning and colleagues,[5] using pellets of methylcholanthrene inserted into the prostate glands of rats, induced squamous-celled carcinomata, and more recently

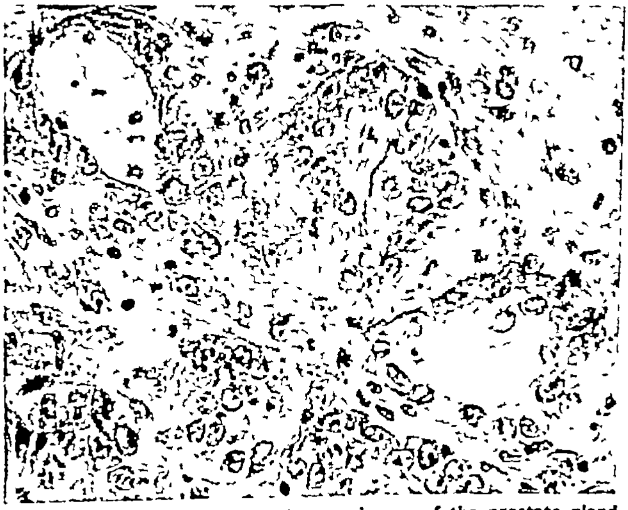

Fig. 1—Section of a primary adenocarcinoma of the prostate gland in a Strong A mouse, induced from normal prostatic epithelium impregnated with crystals of methylcholanthrene and grafted subcutaneously into the belly of a male Strong A mouse. Secretion and cell debris are seen in two alveoli. Several glandular cells are in the process of cell division. This primary tumour has been transplanted and is now in the second passage. (All material was fixed in 'Bouin,' and subsequently stained with Ehrlich's acid hæmatoxylin and eosin.)

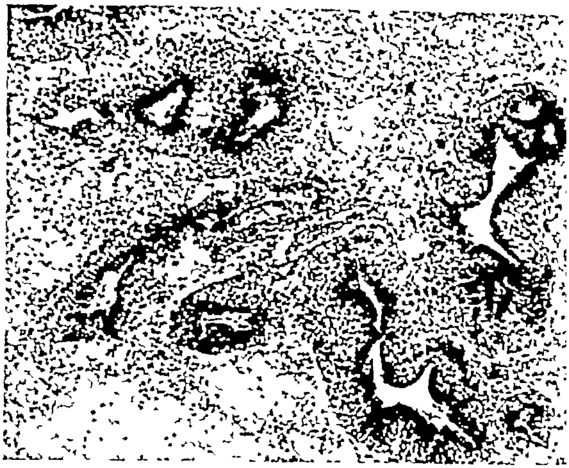

Fig. 2—Section through a glandular carcinoma of the prostate glan a Strong A mouse in the eighth generation of transplants. The tum was induced by impregnating a piece of the prostatic epithelium methylcholanthrene crystals and grafting under the skin.

Horning and Dmochowski [6] obtained transplantable c cinomata by injecting the prostates of pure-line strain m in situ with methylcholanthrene in lard; all these tumo proved however to be squamous-celled carcinoma unlike the common form of prostatic carcinoma in ma

The method adopted in the present experiments l succeeded though on theoretical grounds failure mig have been expected; the fate of homologous grafts ma from adult tissue is usually uncertain. The succe seems partly to be due to the use of a closely inbr strain of mice in which homologous grafting is mu better tolerated than it is in mixed strains. There also reason to believe that results are more uniform the graft is made from a strip of tissue rather than fro a mass of minced fragments, though this point need further investigation. Segregation of the crystals methylcholanthrene by folding the strips of tiss round them would appear to provide the best possib contact between epithelium and carcinogen. The poi of contact between them can be identified more or le precisely, and, further, the carcinogen is shielded by t graft from contact with the host tissues.

In appraising the possible value of transplantab tumours of the mouse prostate for the experiment investigation of prostatic cancer and its hormon treatment in man, it must be admitted that man morphologists do not agree that a strict compariso can be drawn between the various parts of the accesso reproductive glands of primates and rodents.

Whatever homologies one may attempt to dra between the human prostate and the lobulated gland the same name in rodents, it is clear that there exis in the rodent prostate both a fibromuscular stroma an a secretory epithelium identical in the general form of cells with those of the human prostate. Arising like t human gland as a series of outgrowths from the embr onic urethra, the glandular epithelium of the rode likewise depends for the maintenance of its cells on a adequate level of androgen.

It is therefore of great interest to find that, eve although homologies may be uncertain and speci differences often appear to upset the general plan endocrine relationships, the prostatic tumours in mi are surprisingly similar to those found in man, at lea as far as their structural and secretory characters ar concerned. It remains for further experiments t decide whether these similarities can be shown to includ such aspects as relative growth-rates, acid phosphatase secretion, and response to the administration of œstrogens.

MILK MODIFICATION

For Infants and Invalids

Allenburys Dextrin-Maltose consists of rapidly absorbed carbohydrates, chiefly maltose and dextrins, a mixture recognized as highly suitable, in conjunction with milk, for feeding babies, invalids, and persons whose digestive abilities are weak.

It is easily digested, resists fermentation, and counteracts tendencies to diarrhœa. It is better tolerated and may be given more freely than lactose or cane sugar

Its use is indicated in fermentative dyspepsia, in the prevention of diarrhœa (e.g caused by lactose or by bacterial decomposition of carbohydrate), and in undernutrition.

In view of this, the anastomosis should be a retrocolic one close to the duodenojejunal junction.

Mr. A. **Clifford Brewer** had recently collected data on some 362 partial gastrectomies for duodenal ulceration. This analysis was being conducted in the department of surgery of the University of Liverpool. The predominant fact was that where a subtotal gastrectomy was done, with removal of the whole pylorus combined with a Hofmeister stoma, the results were excellent. Where any procedure less than this was performed, and particularly where the pylorus was left behind, results were by no means so good. Where difficulty was encountered from activity of duodenal ulceration, a two-stage operation appeared very satisfactory so long as the second stage was performed within some twelve weeks of the first. It seemed that subtotal gastrectomy was the operation of choice for duodenal ulceration, and in the cases analysed the results had proved eminently satisfactory.

Dr. T. **Cecil Gray** said that spinal anæsthesia probably gave rise to more postoperative chest complications than did general anæsthesia. The improvement today was due not only to a special agent and technique but also, and very largely, to correct preoperative and postoperative care. The importance of good nursing, dental treatment, breathing exercises before and after operation, and active and passive movements to aid the circulation in the recovery period was emphasised. Undoubtedly the use of the barbiturates as the main anæsthetic agent, aided by curare, had enormously improved the prognosis. By exacting criteria the incidence of chest complications in upper abdominal operations was now below 10%.

Dr. H. **Fuld** thought Dr. Kemp had no reason to be gloomy about his figure of 30% for postoperative anæmias. American figures for anæmia following subtotal gastrectomy were 10%; the difference was probably due to the low-grade nutritional anæmia prevalent among hospital patients in this country. Hæmoglobin estimations in 500 unselected patients seen in the surgery during the last twelve months revealed levels of less than 11·5 g. per 100 ml. in more than 20% of patients. In view of the progressive lowering of the operative mortality, it might prove worth while in future to refer patients who developed an ulcer syndrome after the age of forty-five to the surgical expert without much delay.

Reviews of Books

Year Book of Eye, Ear, Nose, and Throat, 1945

Editors: Louis Bothman, M.D.; S. J. Crowe, M.D.; with the collaboration of E. W. Hagens, M.D. Chicago: Year Book Publishers. London: H. K. Lewis. Pp. 540. 18s.

That the fenestration operation has a place in the treatment of the deaf is now incontestable, but a keenly critical approach is still essential. These abstracts show that good results are obtainable in younger patients and in those where bone-conduction is still unimpaired. Cases of so-called catarrhal deafness may be more suitable than otosclerotics, but the differential diagnosis may vary from difficult to impossible. Technique is evidently becoming standardised, and the endaural approach is favoured by American surgeons. Deafness and cataract associated with maternal rubella in early pregnancy have been established as developmental deformities. A large number of abstracts deal with the use of chemotherapeutic substances in different areas of the eye and upper respiratory tract, and some good results obtained with penicillin in cases of intrinsic bacterial allergy are specially interesting. Both surgery and irradiation for laryngeal carcinoma receive support, though both are still crude. Fresh work on the surgical treatment of laryngeal or tracheal stenosis is reported. Treatment of disorders of the ocular muscles is still being revised. Again the bulk of the abstracts are from American literature, and again the high editorial standard is maintained.

Juvenile Delinquency in New Zealand

A Preliminary Study. Eileen Philipp. New Zealand: Council for Educational Research. London: Oxford University Press. Pp. 140. 7s. 6d.

The need for up-to-date and reliable facts about the underlying causes of juvenile delinquency is widely recognised. A valuable contribution to the subject is promised by this book which provides a preliminary study of the nature and extent of juvenile delinquency in New Zealand during the years 1938–45. The writer was trained in the social-science department of an English university and has had wide experience in various branches of social case-work. The figures analysed reveal a striking difference in the proportion of cases of theft to other offences in New Zealand compared with other countries, the proportion being roughly 30% lower than, for example, in England, U.S.A., or Australia. This is thought to be attributable to the very much more uniform social and economic conditions prevalent in New Zealand. The information available also suggests a relatively heavy incidence of delinquency among Maori boys, in all probability associated with the lamentable housing conditions, although it is thought that unintentional discrimination, and readiness to bring a Maori child before the court, may have some bearing on these figures. The main body of the book is concerned with an attempt to draft a form on which a summary of the social history can be recorded for the information of the children's court. A novel feature is the fact that the personal social histories are obtained from the delinquents themselves. The summaries, of which five examples are given, illustrate the complexity of the influences to which delinquency has been a response, and, as the writer says, should help "to correct the over-simplified ideas on causation still widely current." Although emphasis is laid on environmental influences as shown by a tendency to recommend removal from the home as an essential part of treatment, the fact that similar circumstances may have very different effects upon the behaviour of individual children is not overlooked. Useful suggestions are made regarding the lines along which further study of delinquents might be pursued.

Manual of Diagnosis and Management of Peripheral Nerve Injuries

Robert A. Groff, M.D., lieut.-colonel, M.C.A.U.S., formerly assistant professor of surgery, Jefferson Medical College; Sara Jane Houtz, B.S., first lieutenant (P.T.) A.U.S. London: J. B. Lippincott. Pp. 188. 30s.

This little book, written primarily for physiotherapists, deals shortly with the anatomy, injuries, symptomatology, and treatment of peripheral nerve injuries. A full account of the tests of muscle function, including line drawings illustrating every test described, is followed by a series of beautiful anatomical drawings of the regions of the body most susceptible to nerve injury. The physiotherapist will find the first section easily read, and its subject matter should be sufficiently comprehensive for examination purposes. The section on muscle testing is detailed and useful for reference. The anatomical diagrams are no doubt of use to a student who is only concerned with the anatomy of the nerve and muscle, but have less to recommend them to doctors, to whom the book is also dedicated.

Heredopathia Atactica Polyneuritiformis

A Familial Syndrome Not Hitherto Described. Sigvald Refsum. Oslo: Johan Grundt Tanum. Pp. 303.

This book deals with an intensive study of two unrelated Norwegian families in which the author finds evidence of a disease not previously recognised, and which he has named heredopathia atactica polyneuritiformis. One or more of the five persons in these two families presented signs of hemeralopia, atypical retinitis pigmentosa, chronic polyneuritis, ataxia, and other cerebellar phenomena. Three patients showed electrocardiographic signs of sinus tachycardia. Lumbar puncture showed albumino-cytological dissociation with a normal cell count and a great increase of the albumin and globulin content. He thinks the syndrome hereditary, and promises further light on it when pathological anatomical studies by his colleague, Dr. Cammermeyer, on the patients coming to post-mortem examination have been completed.

Death in the Fireplace

It has been demonstrated beyond question that in the homes of the people we neglect the most elementary precautions against accident, and wantonly permit hazards that would arouse a public scandal in the most primitive factory or workshop. This is particularly vicious because the persons at risk in the home—chiefly old folk and children—are less disciplined and less able to look after themselves than adult workers in a factory. Nearly two years ago Wright[1] drew a sombre picture of avoidable suffering and death in the home, caused by burns and scalds. Since then further studies have been pursued in the Birmingham Accident Hospital; and in March of this year Gissane[2] confirmed Wright's findings and urged *immediate action to enforce the provision of* fire-guards and to abolish highly inflammable materials for clothing. Another solemn and urgent warning now comes from Colebrook.[3] Looking first at the loss of life, he points out that, although there has been a substantial reduction in fatal burning accidents during the last two generations, no less than 6516 people in England and Wales died from these causes in the quinquennium 1935–39—and that 2825 of the victims were children. He estimates from his own data that more than 90% of the deaths followed burning and scalding in the home rather than at the place of work.

This shocking waste of life reflects only feebly the sum of human suffering and the loss to the community as a whole. Few calamities leave deeper scars on mind and body. It is true that recent advances in the control of infection have done much to save life and to relieve suffering; and the great achievements in plastic surgery go far to mitigate the permanent disability; but the sum of misery to the victim and his relatives is still enormous. The loss to the community is hard to assess. In terms of working days Colebrook gives a conservative estimate, based on hospital experience in Glasgow and Birmingham, of an average disability of 50 days for severe cases, and of 20 days for those treated as outpatients Taking no account of the patients treated at home, this gives an annual total of more than a million man-days, and there is a similar total for "child-days" lost to schooling. Burning accidents, moreover, represent a serious expenditure in hospital and other medical and nursing services. The inpatients alone account for about a million bed-days a year, and outpatient services are heavily taxed because of the well-known tendency of burns to slow healing in the later stages of recovery, and the frequent need for protracted physiotherapy.

In his survey of the historical background of burning accidents in the home Colebrook remarks on some puzzling features. As one might expect, there has been a considerable fall in the total number of fatal burning accidents, especially in the age-group 0–4 years, during the past fifty years, while in people over 65 the number of deaths has steadily increased. But the sudden drop, far more pronounced in burns than scalds, immediately after the first world war is more difficult to account for. There is clearly a need here for a more detailed statistical analysis. In recent years fatal scalding accidents in children under 5 have involved more boys than girls; but the number of deaths from burning, at all ages over 4, has been much higher among females than males, especially in little girls and old women. We do not know nearly enough about the figures in relation to the population at risk, but some of the factors involved in the reduction in fatal accidents can be put forward with confidence:

1. The replacement of naked candles, gas lights, and oil lamps by electric lights. Candles used by the bedside are still a cause of burning accidents, as Wright showed in her Glasgow investigation.

2. The substitution of modern gas and electric cooking appliances for the open fire and the monstrous kitchen range. Unfortunately a vast number of dwellings occupied by the lower income groups must still rely on obsolete and dangerous appliances, and many burning and scalding accidents are directly or indirectly due to their use. The unprotected gas-ring, often laid on the floor for want of space, is also a villain of the piece.

3. The use of fire-guards (made compulsory when there are children under 7 years in the home) may have had some influence, but Colebrook points out that there is no evidence of this in the returns of the Registrar-General for the years following 1908, when the Children Act introduced this provision. The fact is that the law has always been weakly enforced and in recent years neglected altogether. It should be remarked also that the protection of modern gas and electric fires is often lamentably deficient.

4. The shortening of skirts and the wearing of trousers—especially pyjamas—by women and children has made for greater safety, though not to the same degree in the lower income groups. "On the other hand," Colebrook says, "the change from woollens and tweeds to highly inflammable cotton and silk frocks, nightdresses, dressing-gowns, and underwear has certainly increased the danger of burning accidents." It is doubtful whether this comment can be sustained: the children of the poor have worn inflammable flannelette nightgowns for generations, and countless burning accidents have been reported from this cause.

The home background of all these accidents is a web of the commonplace; the tragedy lies in the fact that we do so little about it. In the broadest sense, bad housing and overcrowding are the principal ministers of death. There is no room for the children to play, except around the grate. Kettles and saucepans are often upset, because the grates are ill designed or out of repair. Overcrowding of both persons and equipment makes it difficult to keep dangerous things in safe places, and to prevent children from interfering with them. Fire-guards for coal, gas, and electric fires are absent or utterly inadequate. The garments of women and children are commonly made of

Death in the Fireplace

It has been demonstrated beyond question that in the homes of the people we neglect the most elementary precautions against accident, and wantonly permit hazards that would arouse a public scandal in the most primitive factory or workshop. This is particularly vicious because the persons at risk in the home—chiefly old folk and children—are less disciplined and less able to look after themselves than adult workers in a factory. Nearly two years ago **Wright**[1] drew a sombre picture of avoidable suffering and death in the home, caused by burns and scalds. Since then further studies have been pursued in the Birmingham Accident Hospital; and in March of this year **Gissane**[2] confirmed **Wright**'s findings and urged immediate action to enforce the provision of fire-guards and to abolish highly inflammable materials for clothing. Another solemn and urgent warning now comes from **Colebrook**.[3] Looking first at the loss of life, he points out that, although there has been a substantial reduction in fatal burning accidents during the last two generations, no less than 6516 people in England and Wales died from these causes in the quinquennium 1935–39—and that 2825 of the victims were children. He estimates from his own data that more than 90% of the deaths followed burning and scalding in the home rather than at the place of work.

This shocking waste of life reflects only feebly the sum of human suffering and the loss to the community as a whole. Few calamities leave deeper scars on mind and body. It is true that recent advances in the control of infection have done much to save life and to relieve suffering; and the great achievements in plastic surgery go far to mitigate the permanent disability; but the sum of misery to the victim and his relatives is still enormous. The loss to the community is hard to assess. In terms of working days **Colebrook** gives a conservative estimate, based on hospital experience in Glasgow and Birmingham, of an average disability of 50 days for severe cases, and of 20 days for those treated as outpatients. Taking no account of the patients treated at home, this gives an annual total of more than a million man-days, and there is a similar total for "child-days" lost to schooling. Burning accidents, moreover, represent a serious expenditure in hospital and other medical and nursing services. The inpatients alone account for about a million bed-days a year, and outpatient services are heavily taxed because of the well-known tendency of burns to slow healing in the later stages of recovery, and the frequent need for protracted physiotherapy.

In his survey of the historical background of burning accidents in the home **Colebrook** remarks on some puzzling features. As one might expect, there has been a considerable fall in the total number of fatal burning accidents, especially in the age-group 0–4 years, during the past fifty years, while in people over 65 the number of deaths has steadily increased. But the sudden drop, far more pronounced in burns than scalds, immediately after the first world war is more difficult to account for. There is clearly a need here for a more detailed statistical analysis. In recent years fatal scalding accidents in children under 5 have involved more boys than girls; but the number of deaths from burning, at all ages over 4, has been much higher among females than males, especially in little girls and old women. We do not know nearly enough about the figures in relation to the population at risk, but some of the factors involved in the reduction in fatal accidents can be put forward with confidence:

1. The replacement of naked candles, gas lights, and oil lamps by electric lights. Candles used by the bedside are still a cause of burning accidents, as **Wright** showed in her Glasgow investigation.

2. The substitution of modern gas and electric cooking appliances for the open fire and the monstrous kitchen range. Unfortunately a vast number of dwellings occupied by the lower income groups must still rely on obsolete and dangerous appliances, and many burning and scalding accidents are directly or indirectly due to their use. The unprotected gas-ring, often laid on the floor for want of space, is also a villain of the piece.

3. The use of fire-guards (made compulsory when there are children under 7 years in the home) may have had some influence, but **Colebrook** points out that there is no evidence of this in the returns of the Registrar-General for the years following 1908, when the Children Act introduced this provision. The fact is that the law has always been weakly enforced and in recent years neglected altogether. It should be remarked also that the protection of modern gas and electric fires is often lamentably deficient.

4. The shortening of skirts and the wearing of trousers—especially pyjamas—by women and children has made for greater safety, though not to the same degree in the lower income groups. "On the other hand," **Colebrook** says, "the change from woollens and tweeds to highly inflammable cotton and silk frocks, nightdresses, dressing-gowns, and underwear has certainly increased the danger of burning accidents." It is doubtful whether this comment can be sustained: the children of the poor have worn inflammable flannelette nightgowns for generations, and countless burning accidents have been reported from this cause.

The home background of all these accidents is a web of the commonplace; the tragedy lies in the fact that we do so little about it. In the broadest sense, bad housing and overcrowding are the principal ministers of death. There is no room for the children to play, except around the grate. Kettles and saucepans are often upset, because the grates are ill designed or out of repair. Overcrowding of both persons and equipment makes it difficult to keep dangerous things in safe places, and to prevent children from interfering with them. Fire-guards for coal, gas, and electric fires are absent or utterly inadequate. The garments of women and children are commonly made of material that burns like a torch. Beneath all these objective factors lies human failure through carelessness, stupidity, and neglect of elementary precautions.

[3] Colebrook, L. *Mon. Bull. Min. Hlth & E.P.H.L.S.* October, 1946, p. 214.

The situation calls for immediate action. Cheap and efficient fire-guards, preferably fixed or hinged to the appliances, should be designed, and their use enforced by law. The manufacture of dangerous fittings ought to be forbidden under a safety code of standards. As COLEBROOK says, the level of awareness of danger can be raised among older children and adults by propaganda, films, radio talks, exhibitions, and other educational measures: "Such propaganda would necessarily encourage the general use of effective well-designed fire-guards; of clothing for children and women which is relatively fireproof (this should be certified by appropriate markings on the material); of fittings on the top of gas and electric stoves which would make it difficult to upset saucepans and kettles." Manufacturers of appliances and of clothing might well lead the way; and local authorities planning houses should review the safety measures which ought to be taken. To frame a long-term policy of safety in the home we need far more information than we possess today. The causes of minor burning accidents may show a different distribution from those of serious cases. More effective measures of prevention may be found when we know more about causes. A comprehensive survey is not easy to organise, but there are many willing helpers. The department of the chief scientific adviser to the Ministry of Works, in coöperation with the Ministry of Health, has already started a series of investigations, and the assistance of medical officers of health, housing managers, medical practitioners, and others is being sought. It is important that a long-term policy should be founded on accurate and comprehensive knowledge, but we know enough to take immediate measures of protection.

Splenectomy

THE oddest thing about the spleen is that it should exist at all as a separate organ. It is an unpaired structure of considerable size, complex design, and exceedingly rich blood-supply; yet its total removal is compatible with perfect health. Indeed, if we are to believe the ancients and the evidence of more recent animal experiment, its presence is a positive embarrassment to those who aspire to athletic distinction. Every student knows that the spleen is a part of the reticulo-endothelial system and that it is therefore concerned with such matters as the formation of lymphocytes, the destruction of erythrocytes, the elaboration of antibodies, and the metabolism of lipoids, blood-pigments, iron, and possibly purines. But the only positive function which the spleen as a separate structure appears to subserve is to hold in reserve several hundred cubic centimetres of blood which can be added to the circulation in the emergencies of violent exercise anoxæmia or hæmorrhage. Many other functions have been postulated, only to remain, for lack of evidence, fascinating speculations. Perhaps the most interesting of these hypotheses is that the spleen exerts a hormonal influence on the bone-marrow and that the benefits of splenectomy for thrombocytopenic purpura and Banti's disease are derived from abolition of this influence. The mystery surrounding its functions and the doubts which exist on the indications for its removal must responsible for the large volume of surgical writing on the spleen. It would otherwise be curious surgeons should pay so much attention to an for which there is, in practical effect, only one surgical procedure—to wit, excision.

There are three absolute indications for tomy: rupture, familial acholuric jaundice (usually called spherocytic icterus in the United States) and primary thrombocytopenic purpura. Rupture of the spleen, whether its symptoms are manifested at once or delayed, and whether it occurs in a normal or a diseased organ, is perhaps the only indication for operation on the spleen in which the surgeon knows the precise reason for his intervention and why the operation is curative—it stops an almost invariably fatal intraperitoneal hæmorrhage. The rationale for splenectomy in acholuric jaundice is not so definite. It prevents the spleen from destroying a blood cells, but in some cases the erythrocyte fragility is restored to normal by the operation, suggesting that the spleen may play a more complicated rôle than that of destructor and may influence the erythroblastic activity of the bone-marrow. Whatever the underlying explanation of the results, they are so good in practice that splenectomy is abundantly justified. Much the same is true of primary thrombocytopenic purpura. Here the results are very satisfactory provided the case is really primary and not connected with menstruation, pregnancy, or drugs; some authorities maintain that the disease is due not to excessive platelet destruction by the spleen but to its more oblique activity in inhibiting megakaryocytes. One might add to these three absolute indications a fourth class to contain those often described but seldom seen entities, ectopia, cysts, and primary tumours of the spleen, but here the diagnosis is seldom made before the abdomen has been opened.

There are some diseases in which the effects of splenectomy are so uncertain that they constitute a relative indication for operation. Banti's syndrome heads this list, and the work of the spleen clinic of the Columbia Presbyterian Medical Centre, lately reported by WHIPPLE,[1] has gone far to explain the uncertain results of splenectomy in this disease. The cause of the enlarged spleen is portal hypertension, and WHIPPLE has relieved the signs and symptoms in advanced cases by anastomosing the portal vein to the vena cava. He believes that splenectomy is helpful only where the splenic vein alone is obstructed and that it will do harm in most cases by destroying useful collateral channels. WHIPPLE does not discuss the cause of the anæmia in Banti's syndrome and one is left to wonder whether erythrocytes dammed back in an enlarged spleen naturally suffer abnormal destruction or whether the spleen has exerted a sinister influence on erythropoiesis. STIVEN[2] has reported favourable results from splenectomy in Egyptian splenomegaly, a condition which clinically resembles Banti's syndrome; but since this is probably a manifestation of schistosomiasis, the benefits of splenectomy must fall short of cure. There are further conditions in which the removal of a vast spleen, though not curative, affords great mechanical relief, and chronic malaria and kala-azar, as well as Gaucher's disease, may on rare occasions benefit thus from operation. Lastly, there is the group of cases distinguished by Prof. C. A. DOAN of Ohio—primary splenic neutropenia and panhæmatopenia—in which a persistent neutropenia in the former and anæmia, neutropenia, and thrombopenia in the latter are accompanied by signs of overactivity in the corresponding bone-marrow cells; DOAN recommends splenectomy for both these conditions.

[1] Whipple, A. O. *Ann. Surg.* 1945, **122**, 449; see *Lancet*, 1946, i, 743.
[2] Stiven, H. Société Internationale de Chirurgie, 10th Congress, 1936.

The contra-indications to splenectomy are important. It is obviously useless where a moderate splenic enlargement is a manifestation, but not an essential part, of a generalised disease. Thus in Hodgkin's disease and lymphosarcoma splenectomy is a mistake. In leukæmia it is a fatal mistake. Its problematical benefits in pernicious anæmia have been displaced by liver therapy, and in icterus gravis neonatorum transfusion with rhesus-negative blood is its happy successor. With the proper indications, the mortality of splenectomy can be minimal. PUGH,[3] in a recent review, points out that the mortality for the original operation was 100%, but that this figure has now improved almost to zero. At the Mayo Clinic, for 1003 cases operated on over forty years, the figure was 9·4%; at the Lahey Clinic in Boston there has not been a single operative death from splenectomy since 1941; PUGH himself reports 15 splenectomies in which there was only 1 death, and that was reasonably attributed to a severe intracranial injury. It is likely that most surgeons would put the mortality of splenectomy at about 10%; but in fact, if traumatic cases are excluded, this is too high; the key to success is really effective coöperation between physician and surgeon in the selection of cases and the time for operation, and in the management of convalescence.

An essential part of splenectomy, except in cases of rupture, is a careful search for spleniculi, which must be removed if permanent results are to be achieved.

Fluorosis—Endemic and Man-made

IT is not yet certain that fluorine is essential to full health, as other trace elements such as iodine are known to be. There is evidence, however, that when optimal amounts are available during growth it increases the resistance of the teeth to caries. Like iodine, fluorine is present in varying amounts in drinking-waters. Unlike iodine, which produces harmful consequences by its defect, fluorine does so by its excess. In various parts of this country, and notably at Maldon, in Essex,[1] it gives rise to dental fluorosis with unsightly mottling of the teeth. In parts of China where it is present in the water in great excess it causes gross skeletal changes with severe disabilities and sometimes death.[2] In at least one or two areas in England where dental fluorosis occurs, osteochondral changes in the vertebræ have been discovered in adolescents; it seems probable that an association of fluorosis with poor social and nutritional status is here responsible.[3]

In addition, however, to endemic fluorosis there is another hazard present in and near certain industries which give rise to fluorine fumes or smokes. Elsewhere in this issue Dr. MARGARET MURRAY and Dr. DAGMAR WILSON give a useful summary of information bearing on both endemic and man-made fluorosis, together with a report of a local "incident." HUNTER [4] and his colleagues have studied the industrial and some of the secondary neighbourhood risks of fluorine smokes evolved by aluminium works. Grass and crops may be contaminated, especially on the leeward side of certain industries, to a considerable distance, and disease and death in sheep and cattle due to cropping of contaminated grass have been reported.[5] [6] MURRAY and WILSON discuss the fuller public-health and social consequences of such a hazard in the neighbourhood of an area devoted during the war to surface iron-ore calcination. They mention further that some 28 industries in this country give rise to fluorine emanations, and suggest that the nature and degree of the risk to farm stock and human beings is not at present sufficiently appreciated by those responsible for all the industries concerned or by local authorities.

No such catastrophe as the "fog disaster" in the Meuse valley in 1930 has been recorded in the British Isles. On this occasion a thick cold mist lay over parts of Belgium. The smoke from a number of factories became mingled with the fog. Several thousand people developed pulmonary symptoms and there were 60 deaths, chiefly among old people. Of the 27 factories in the neighbourhood, 15 employed fluorine-containing substances involving the possibility of passing gaseous fluorine compounds into the chimney smoke.[7] Window-panes and electric bulbs lost their gloss more quickly than usual. Cattle, after grazing a short time, contracted serious bone disease; but, as the bony effects of fluorosis are very slow to arrive, this evidence must be accepted with caution. The whole episode was held to incriminate fluorine as the probable chemical cause of the disaster.

Such a combination of adverse circumstances is unlikely to be repeated, but, even were it impossible, there is clearly a case for the more detailed study of specific chemical hazards of this kind. We do something approaching our best to protect water and food from contamination, but the air we breathe can still be a source of danger. According to a recent statement by Mr. HERBERT MORRISON, as reported in the daily press, atmospheric pollution costs us £50 million a year, irrespective of its effects on the health of the people and their amenities. A great deal of this pollution is preventable. Some of the waste-products of industrial processes—fluorine among them—are not only recoverable but valuable. It seems that a major cause of delay in handling problems of this kind may be the lack of machinery for coördination between industry, the public-health services, a number of Government departments, and those research-workers who by their individual or collective initiative disclose evils we must all desire to abolish.

Annotations

A POSTGRADUATE SCHOOL AT CAMBRIDGE

In 1944 the Goodenough Committee pointed to an opportunity at Cambridge to develop a postgraduate centre for doctors from this country or overseas who want advanced and specialist training. A beginning, they suggested, might well be made by setting up research and training units based on Addenbrooke's Hospital and on "the strong departments already existing in the University in the fundamental sciences." Part of this plan has become fact. The university has established departments of experimental medicine and radiotherapeutics for which the hospital is providing beds. Beds have also been put at the disposal of the regius professor of physic, and the honorary staff of the hospital has been strengthened by additional appointments. Further arrangements have now been made for the university to assume responsibility for the pathological and biochemical services of the hospital. Hitherto the university departments of pathology and biochemistry have been concerned only with research and teaching. Now their work is to cover clinical and pathological material from the hospital, and bacteriological and epidemiological material from the East Anglian region; and Dr. A. M. Barrett, Dr. M. H. Gleeson White, and Dr. N. R. Lawrie have respectively been appointed university morbid anatomist, bacteriologist, and biochemist to Addenbrooke's.

So far has been so good that the university and hospital have decided that they are now ready to carry the scheme a big step further, and a school of clinical research and postgraduate teaching is to be initiated, consisting of the departments of experimental medicine and therapeutics (already in being) in association with the university departments of medicine, anatomy, pathology, biochemistry, experimental psychology, and physiology. The regius professor of physic will be chairman of the council of the school, which will include the heads of the departments, and representatives of the faculty boards concerned, the general faculty board, and the general committee and the honorary staff of Addenbrooke's.

It is intended that the school shall share a common site with Addenbrooke's, and its research wards are to be an integral part of the hospital. But according to contemporary custom the scheme must await the builders, and until new premises are erected the hospital will assign some of its own beds to the new departments. The heads of the departments of the school will be elected to the honorary staff of the hospital, and arrangements are being made for the university to be represented on the general committee in whose deliberations they already take a friendly if informal part.

Under the National Health Service Act the hospital and specialist services of the area will be associated with the university, and it is hoped that Addenbrooke's will be designated a teaching hospital. The university has further announced that it is prepared, once the postgraduate school is well established, to consider the possibility of starting a pregraduate school of clinical teaching. The future clearly holds further opportunities and Cambridge is preparing for them.

THE UNMARRIED MOTHER

The illegitimacy-rate, which had been falling steadily since the beginning of the century, was down to 42 per 1000 live births in 1939, but rose with the war, to reach 72 per 1000 in 1944. In a new broadsheet [1] P.E.P. note that two-thirds of the mothers of illegitimate children return either to their family home, to the child's father, or to their legal husbands. The remaining third, who have neither home nor friends behind them, experience social and financial penalties which have changed relatively little since the last century. "Unfortunately, there are still some voluntary hospitals which do not admit unmarried mothers and demand to see the marriage lines of all women applying for beds in public (but not in private) maternity wards." Maternal mortality continues to be higher among single than among married mothers, and the rates for infant mortality, stillbirth, and neonatal death are higher among illegitimate than among legitimate infants. Some of the reasons for the greater risks to the illegitimate child were set out by Dr. G. F. Buchan [2] several years ago. During her pregnancy the mother has to keep herself and prepare for the child; so she may work almost until her confinement. Then, after ten days or a fortnight in hospital, she is discharged, often with nowhere to go, needing to get work at once. Not knowing how to find a foster-parent, she persuades someone to take the child, on a promise of payment out of her first earnings; and if work is not found at once the foster-mother may refuse to keep the child.

There have been advances since Dr. Buchan wrote his article, but not yet on a wide enough scale. The mother can sometimes stay on in a postnatal hospital for a time, breast-feeding her baby and giving domestic help in exchange for her keep. But this is only a temporary measure, and one which some mothers are unwilling to accept; moreover places in such hostels are scarce. The mother's best—almost her only—chance of keeping the baby with her is to take a resident domestic post. If she is unfitted or unwilling to do this she must leave the child in a day nursery while she goes to work, or find lodgings where the landlady is willing to look after the child: but again such landladies are rare, especially in the present housing shortage. Most homeless mothers must consent to be separated temporarily or permanently from their children, placing them in residential nurseries (though these are now fewer than they were during the war) or with foster-parents (now as uncommon as friendly landladies), or allowing them to be adopted, the arrangement often being made casually in a pub or a queue. In the opinion of P.E.P.—

> "A mother, whether married or unmarried, who is without a breadwinner, should be enabled to earn her living and to keep her child with her. This is a problem of lodgings, of sufficient accommodation in day nurseries, and of residential nurseries for emergencies. Working mothers' clubs or hostels with bed-sitting rooms, gas-rings, and nurseries attached might go a long way in solving it; they should be part of the local authority's services for homeless mothers."

Because of the moral issues linked with the question of illegitimacy, most voluntary bodies caring for the welfare of the unmarried mother are religious. Unfortunately there is very little central coördination, and the efficiency of different homes varies very greatly. The religious organisations include the Salvation Army, which never refuses a case, the Church of England Moral Welfare Council, Roman Catholic Diocesan homes, and a few Free Church homes (the last three rarely take second pregnancies, and cases with venereal disease are rigidly segregated in separate homes). There are also some non-denominational homes and hostels. Some of these variously sponsored homes are run on modern lines; others lock their doors, open all letters, and remove all money and notepaper from the residents. There are only about 8 homes for mothers with venereal disease, but it is possible that with modern methods of treatment it may no longer be necessary to segregate such cases.

In November, 1943, the Minister of Health encouraged welfare authorities to meet their responsibilities in this field. He had a good response, 339 schemes being submitted, in 210 of which a moral-welfare association was being asked to coöperate, while in 50 specially qualified social workers were to be appointed, and in others health visitors were to be specially instructed. The homeless mother badly needs the support of an experienced social worker. By the end of 1944 seven new hostels for unmarried mothers and their babies and three residential nurseries had been, or were about to be, opened, and many authorities, following one of Dr. Buchan's suggestions, were arranging to find suitable foster-mothers and to guarantee their payment. P.E.P. would like to see services for the unmarried mother and her child centred in the Ministry of Health and administered as part of the National Health Service. Antenatal and postnatal homes are needed for all maternity cases, and would help to prevent the undesirable segregation of unmarried mothers.

PULMONARY ŒDEMA

THERE is now much evidence, both in animals and man, that injected protein solutions usually leave the circulation rapidly, and that protein is removed as well as water and salts. Nevertheless the conception of fixed circulating proteins is still prevalent, and the suggestion is made that an attempt to increase their concentration in the blood will result in large quantities of œdema fluid being drawn out of the lungs.

Writing on pulmonary œdema lately in these columns, Courtice and Foss[1] reached conclusions which seemed diametrically opposed to those of Cleland.[2] But it is essential here to differentiate between two distinct types of pulmonary œdema—that following exposure to irritant gases, and that resulting from an acute rise of pressure in the pulmonary veins. Courtice and Foss studied the former type in dogs and goats and found that injected protein solutions will not correct the hæmoconcentration which follows exposure to phosgene. Arterial oxygen saturation was not followed, but their animals died more rapidly after injection of plasma or serum, presumably from increasing pulmonary œdema. Courtice and Foss conclude that transfusions in the presence of gross pulmonary œdema are therefore definitely detrimental. As Daly[3] has pointed out, however, it is difficult to correlate the results of animal experiments with different types of pulmonary œdema in man.

The second type of pulmonary œdema is commonly seen in lesions of the left side of the heart, but it also occurs when the heart is more normal, as in transfusions after hæmorrhage. The sequence of events is generally thought to be as follows. Initially there is an acute rise of pressure in the pulmonary venous system, and dyspnœa which is probably reflex from this rise of pressure. Peripheral arteriolar constriction occurs and the blood-pressure rises. Cyanosis at this stage is not due to diminished arterial oxygen saturation but to peripheral constriction. The rise of blood-pressure adds to the work of the heart, and dyspnœa probably increases the already high pulmonary venous pressure. Only terminally does arterial oxygen saturation show a conspicuous decrease. All intravenous infusions raise the venous pressure to greater or lesser degree, so that it is difficult to believe that injected protein solutions can do anything but harm in this type of case. Although data obtained in the field are necessarily incomplete and difficult to assess, the clinical improvement observed in some of Cleland's cases after the intravenous injection of concentrated plasma may have been due to the raising of a low venous filling pressure which had resulted from an acute reduction of blood-volume from hæmorrhage or plasma loss.

In the streets of a big city it is not uncommon to see an elderly hypertensive person in the throes of an attack of acute left heart-failure. Well-meaning but misguided bystanders will often attempt to increase the venous pressure still further by insisting that the sufferer should lie flat. There is no reason why the informed physician should follow such courses.

ARBUTHNOT LANE

Lane was a lion among surgeons, and none the less so because everything that he did led not to critical discussion but to disagreement and contention. In his prime he had three enthusiasms: for operation in cleft-palate children (by an extension of Davies-Colley's flaps) at the earliest possible age and if possible within 24 hours of birth; for fixing every fracture of a long bone with an internal splint, again as early as possible; and for the removal of the colon for a condition, sensed rather than described, which he called "chronic intestinal stasis." The time has not yet come to write a final appreciation of this work—emotion would still sway reason too much—but the time has come to record the dates in his life. This Mr. W. E. Tanner[1] has done, and he has prefixed a chapter on his own life to show how Lane inspired the young men around him.

What was this wizardry that had so great an influence on those with whom and for whom Lane worked? For his patients felt it as strongly as his house-surgeons and were impelled to get well, sometimes from things quite outside those for which their operation had been performed. It lay in his idealism and his sympathy. Like Lister, Lane had an intense sympathy for group humanity, and each of the operations at which he worked was inspired by this. By his cleft-palate operation he strove to give life and human speech to children born with the commonest of the distressing deformities with which human beings come into the world. By his bone-plating he aimed to help the working man, and especially the casual labourer who was thrown out of work when he could not carry a 2 cwt. sack and faced starvation, because in those days there was no sickness benefit, no unemployment insurance, and no workmen's compensation—only the Poor Law Act of 1836, under which he was grudgingly given outdoor relief which meant the loss of his civil rights. Lane threw aside æsthetic estimations of the results of fracture treatment, such as good alignment, and replaced them by standards based on wage-earning capacity. If a man could not return to the work he did before he broke his leg the treatment of that fracture was a failure; and it was this ideal that makes Lane one of the founders of orthopædics. And lastly that sad little group of shrivelled up, greasy-skinned sour-tempered middle-aged women in sympathy for whom he started to open the abdomen; but instead of removing the ovaries or appendices or sewing up the kidneys or the uterus, as other surgeons were doing, Lane concentrated on the gut and therefore devised a hypothesis and an operation. The type of women for whom he did a colectomy have disappeared today, but it was sympathy for their very genuine misery that made Lane try to do more than merely pass them on to a different outpatients' department.

With his sympathy Lane combined a standard of idealism which taught that you must always have an ideal but must never attain to it, for when you find yourself doing so you must push it further away; and with this he incorporated a conscientious scepticism which held that when there was anything in surgery on which all were in agreement it was almost certainly wrong. No man at Guy's more fully followed the motto of the hospital—that it is better to give than to receive. In some ways he received greatly, but whether he took a big fee or only lifelong gratitude he always gave the patient something more than he had taken from him. We must thank Mr. Tanner for bringing out a life of this great man at a time when there is some need of emphasis on these points.

PHASE-CONTRAST MICROSCOPY

OBSERVATION of the living cell by transmitted light has been a difficult task, for the refractive indices of the unstained components vary only slightly, and the thickness of a single cell is insufficient to make minor variations observable. Dark-ground illumination is a useful supplementary technique, and intravital staining has yielded further information. Ultraviolet microscopy requires special apparatus and the irradiation kills most tissues fairly rapidly, while the interpretation of observations made on the classical stained section is suspect, for one cannot eliminate the possibility that artefacts are produced by the staining technique. Electron microscopy is still for the few. The phase-contrast technique, first suggested ten years ago, was demonstrated to a meeting of the optical group of the Physical Society on Nov. 22. This brings to a successful conclusion the work of Mr. C. R. Burch, PH.D., F.R.S., and his colleagues at Bristol, who have long championed the idea and at this meeting presented a mathematical analysis of the principles involved.

The phase-contrast technique employs a system for retarding part of the beam incident on the microscope condenser; this is modified in passing through the specimen, and the emergent beam collected by the objective passes through another retard plate placed accurately over the first. The effect is to accentuate by interference the minor differences in phase introduced by the tissue, and so to render visible changes in optical density imperceptible by normal observation. Mr. A. W. Hughes, PH.D., spoke of the tremendous progress now possible in cytological studies, and showed two films made at the Strangeways Laboratories with a home-made simplification of the equipment. This development has also been studied in Germany, and a few examples of the Zeiss equipment are in England. Two speakers remarked that the recently developed British equipment is superior to the German. Old prejudices die hard, but it is time that the old wives' tale that English microscopes are not as good as Continental was discarded.

THE DISPUTE

IT is difficult to write temperately of the decision of certain local authorities to discharge anybody in their service who refuses to join a trade union. Yet presumably this decision seems to them entirely reasonable. "It is generally accepted," says the *Encyclopædia Britannica*, "that the conduct of industrial negotiations in Great Britain must be on the basis of negotiations between organised workers and organised employers," and during the war of 1914–18 the Government themselves, and many employers, encouraged workers in the larger industries to join a union. In big organisations it is obviously more convenient that terms of service should be agreed with the whole body of workers rather than with individuals separately, and there must be a mechanism for appointing plenipotentiary representatives. To a considerable proportion of the people of this country it has become an article of faith that the decent man joins a union so as to stand by his comrades; and those who refuse to join one incur scorn because they stand aside yet profit by the union's efforts—less being said about their suffering through union action of which they may disapprove. When he is elected to the control of a municipal service, the trade unionist naturally thinks of it as a rather untidy industry which needs to be set in order, and related to other industries, by giving everyone trade-union status as a worker with appropriate representation. Unfortunately, to achieve so desirable an end he sometimes holds it permissible to use compulsion —employing the direct action which has won the unions so many victories, and so many members, in the past.

There is no need to repeat here the arguments against this variety of compulsion: the indignation aroused by its application in a new field by the local councils ha been vigorously expressed by many newspapers. We feel bound to add, however, that, rightly or wrongly, salar members of the medical and nursing professions do regard themselves as "employees"; when a doc works for a council his primary duty is still towards patient, and his relation towards the council is not relation of "master and man" which obtains in indus and which forms the basis of trade-union organisati It is true of course that the professional status cheris by doctors and nurses may have elements of snobb (as a correspondent argued in our last issue), but w is much more important is that it provides standa and incentives of high social value, which more than e need preserving now that the financial prizes of succ are diminishing. To outsiders at least, it has seemed t whatever else they may have done, trade unions ha seldom inspired their members to work without reg for time or place or anything but the end in view. doctors require such inspiration; and, until we offered something better, we shall continue to w our professional uniform, because it helps to ke us up to the mark and still attracts likely lads our ranks.

We shall be told perhaps that this is quite irrelevan that nobody thinks of challenging professional statu and that for doctors, dentists, and nurses membersh of a trade union is demanded merely as a matter administrative convenience. Of this it will be easier judge when we know precisely how the councils defi "trade union"—whether strictly as a union affiliat with the Trades Union Congress or loosely as any bo representing workers. In recent legislation Parliame has not apparently favoured a "closed shop" in a narrow sense; for example, the Coal Board are instruct to consult with "organisations appearing to them represent substantial proportions of the persons in t employment of the Board, or of any class of such persons. If the local councils want to find organisations represen ing substantial proportions of the doctors in the employment they need go no further than the Britis Medical Association and the Society of Medical Offic of Health, which, though not trade unions, are recognis by the Government and the public as competent represent doctors on questions of service. If the counci confine themselves to asking that doctors and nurs taking their appointments shall belong to an organisati capable of representing them we shall have to admit th they have a case worth considering. But in a reasonab society, such as we are trying to build, such proposa ought to be put forward in the first place for discussi rather than for compliance. The terms of service doctors working for local authorities are largely the resu of agreement on the national level between all t interested parties, and in our view no big change oug to be imposed locally by individual councils followi their own ideas. We believe in fact that local authoriti like workers, should act through the associations form to represent them.

The independent action of the councils has increas the difficulties of moderate men. Apart from its possib effect on the recruitment of nurses, it has provided bonus for those who oppose the Government's plans f a National Health Service, and Mr. Bevan may not fin it easy to undo the damage. At the same time it mus be remembered that under that service the number o doctors and nurses working for local authorities wi be far smaller than at present, and the question o trade-union membership may scarcely arise. One of th merits of the scheme, compared with some of its predeces sors, is that it goes a very long way to take the medica services out of municipal politics.

Special Articles

WORK FOR THE DISABLED

THE scheme for the reablement and settlement of the disabled has benefited greatly by the appointment of the standing committee, under the chairmanship of Mr. H. H. Wiles, to coördinate the work of the responsible departments. They have now reported[1] on the progress of their work up to date, and it makes heartening reading.

The numbers of hospitals in England and Wales offering active reablement have increased from 150 in 1943 to 333 in 1946—thus amounting to nearly 65% of the 520 hospitals selected in 1943 by officers of the Ministry of Health as fitted to develop reablement departments.

In Scotland during the war reablement was concentrated largely in emergency hospitals run by the Department of Health, and in the hutted annexes run by local authorities as part of the Emergency Hospital Scheme. These contain the special units—for neurosurgery, plastic and orthopædic surgery, and so on—set up under the scheme; reablement departments have been developed according to the needs of each institution. At Gleneagles the fitness centre established for miners now accepts any male civilian. The Department of Health is assessing the present reablement facilities in Scotland, and finding out at which hospitals they might be developed in future.

HEART AND LUNG CASES

The London County Council have agreed to start an experimental scheme at the Northern Hospital, Winchmore Hill, for cardiac patients between the ages of 18 and 25, but, owing to staffing difficulties, have not yet been able to set up a centre. More progress has been made on behalf of tuberculous patients: in 1943 memoranda on examination, diagnosis, treatment, and welfare were sent to local tuberculosis authorities; and maintenance allowances are now made to patients during treatment, and paid back to the authority by the Exchequer. The local offices of the Ministry of Labour are collaborating with the tuberculosis authorities in finding work under suitable conditions for patients as soon as they are fit to undertake it. It has proved easier to find part-time work for them than to provide reablement centres, but work in sheltered surroundings is being specially considered.

THE HARD OF HEARING

For the partially deaf a new and efficient hearing-aid has been designed by the electro-acoustics committee of the Medical Research Council. Under the new health service, treatment for deafness, scientific assessment of the need for this hearing-aid, and the aid itself, with service and new batteries, will all be provided. Possibly the aids themselves may be made in factories for the disabled.

THE MENTALLY ILL

Patients with psychiatric disorders are perhaps the hardest of any to settle in work. Two experimental assessment centres—one in England, one in Scotland—are to be set up where patients will be studied and recommended for the most appropriate form of reablement. They will be run on the lines of the Dartford centre set up to help returned prisoners-of-war. In addition, new reablement centres will be established by the Ministry of Labour for people developing neuroses in industry; these will occupy the civil resettlement units taken over from the Forces. Those with mild troubles, including some who have passed through the centres described, will be helped to return to ordinary work, while the more seriously affected will be given work under sheltered conditions, either by the Disabled Persons Employment Corporation or by voluntary bodies, such as the Ex-Services Welfare Society. For those who cannot be resettled in any of these ways new plans will have to be devised; but in the meantime it will be possible to learn much about their numbers and their needs.

MINERS AND DOCKERS

Apart from the Gleneagles Fitness Centre, special factories for miners with silicosis and pneumoconiosis are planned. Merseyside and Manchester dock-workers suffering from minor physical ailments can nowadays get medical advice and be referred for treatment under an experimental scheme, and the committee feel that the development of similar schemes would be useful. They have also studied the Scottish Supplementary Medical Service, which helps general practitioners by providing complete consultant and diagnostic facilities for early cases of organic disease. This scheme, originally limited to the Clyde Basin and to people under 25, has now been extended to people of all ages in every industrial area of Scotland, and is fully supported by doctors.

STAFF TRAINING COURSES

It is thought that the time is not yet ripe for founding a postgraduate diploma in reablement, but some special courses have been held and over 250 doctors have attended them. A new course of training, lasting a year, has been arranged by the Institute of Hospital Almoners, and eligible ex-Service candidates are offered financial help towards taking this. Some 150 physical-training instructors from the Forces are being trained as remedial gymnasts with the help of the Ling Institute.

OPENINGS FOR THE DISABLED

Artificial limbs are still being supplied either free or on a cost-recovery basis to all who need them, and the employment of people with artificial limbs is being encouraged by the Ministries of Labour and Pensions. Under the new Act, artificial limbs are to be provided as a part of the health service. The appointment of disablement resettlement officers (D.R.O.s) was at first not wholly successful because there were no candidates with experience of the special duties required of them. Better training courses are now provided.

Vocational training may be provided under the Act for all disabled people over 16 who need it, and a wide range of occupations and trades are covered, including agriculture, civil engineering, and such divers callings as bootmaking, diamond-polishing, commercial art, pottery, hairdressing, piano-making, watch-mending, spray painting, and many others. Great efforts are made to meet individual requests for forms of training not on the list. The number to be trained is agreed with representatives of the industry, who also ensure that those reaching a given standard of training will be found skilled jobs. Some important industries, however, such as engineering, furniture-making, and printing, can only accept small numbers.

Training for technical and professional occupations is also offered. Up to August 31 of this year 3000 people discharged from the Forces for medical reasons had been given awards under the Further Education and Training Scheme, and applications from another 500 were being considered.

At the residential Industrial Rehabilitation Centre at Egham 200 men can be received at a time. They stay 1–3 months, receiving free board and lodging and a maintenance allowance while they are made fit for work or vocational training. Some Army civil resettlement units are to be taken over by the Ministry of Labour and used for the same purpose. The new centres will not exclude people who have been suffering from neurosis, and at least one will accept women.

In order to be eligible for resettlement under the scheme, the patient must put his name on the register of disabled persons maintained at the local offices of the Ministry of Labour. As a result of the growth of the register, and the existence of unemployed disabled, the Minister of Labour decided to raise the quota of disabled persons to be employed in industry from 2% to 3% on Sept. 1, and the possibility of a further increase is being kept in mind. The two employments of passenger electric-lift attendant and car-park attendant have been designated as specially suited for the disabled, which means that future openings in these occupations will be reserved for them.

The Act gives the Ministry of Labour statutory authority to provide sheltered conditions for those who need them, and in fact for some years the Ministry has

When he is elected to the control of a municipal service, the trade unionist naturally thinks of it as a rather untidy industry which needs to be set in order, and related to other industries, by giving everyone trade-union status as a worker with appropriate representation. Unfortunately, to achieve so desirable an end he sometimes holds it permissible to use compulsion —employing the direct action which has won the unions so many victories, and so many members, in the past.

There is no need to repeat here the arguments agains this variety of compulsion: the indignation aroused b its application in a new field by the local councils ha been vigorously expressed by many newspapers. We fee bound to add, however, that, rightly or wrongly, salarie members of the medical and nursing professions do no regard themselves as "employees"; when a docto works for a council his primary duty is still towards hi patient, and his relation towards the council is not th relation of "master and man" which obtains in industr and which forms the basis of trade-union organisatio It is true of course that the professional status cherishe by doctors and nurses may have elements of snobber (as a correspondent argued in our last issue), but wha is much more important is that it provides standard and incentives of high social value, which more than eve need preserving now that the financial prizes of succes are diminishing. To outsiders at least, it has seemed that whatever else they may have done, trade unions have seldom inspired their members to work without regard for time or place or anything but the end in view. We doctors require such inspiration; and, until we are offered something better, we shall continue to wea our professional uniform, because it helps to kee us up to the mark and still attracts likely lads t our ranks.

We shall be told perhaps that this is quite irrelevant; that nobody thinks of challenging professional status; and that for doctors, dentists, and nurses membership of a trade union is demanded merely as a matter of administrative convenience. Of this it will be easier to judge when we know precisely how the councils define "trade union"—whether strictly as a union affiliated with the Trades Union Congress or loosely as any body representing workers. In recent legislation Parliament has not apparently favoured a "closed shop" in any narrow sense; for example, the Coal Board are instructed to consult with "organisations appearing to them to represent substantial proportions of the persons in the employment of the Board, or of any class of such persons." If the local councils want to find organisations representing substantial proportions of the doctors in their employment they need go no further than the British Medical Association and the Society of Medical Officers of Health, which, though not trade unions, are recognised by the Government and the public as competent to represent doctors on questions of service. If the councils confine themselves to asking that doctors and nurses taking their appointments shall belong to an organisation capable of representing them we shall have to admit that they have a case worth considering. But in a reasonable society, such as we are trying to build, such proposals ought to be put forward in the first place for discussion rather than for compliance. The terms of service of doctors working for local authorities are largely the result of agreement on the national level between all the interested parties, and in our view no big change ought to be imposed locally by individual councils following their own ideas. We believe in fact that local authorities, like workers, should act through the associations formed to represent them.

The independent action of the councils has increased the difficulties of moderate men. Apart from its possible effect on the recruitment of nurses, it has provided a bonus for those who oppose the Government's plans for a National Health Service, and Mr. Bevan may not find it easy to undo the damage. At the same time it must be remembered that under that service the number of doctors and nurses working for local authorities will be far smaller than at present, and the question of trade-union membership may scarcely arise. One of the merits of the scheme, compared with some of its predecessors, is that it goes a very long way to take the medical services out of munic the council in May, 1944, after dismissal from the R.A.M.C. by court-martial for drunkenness, and after conviction by a police-court of driving a motor-car under the influence of drink. The council then postponed judgment for a year. In May and July, 1945, the council decided that it would have been prejudicial to the health of Dr. Robertson for him to attend, and in November, 1945, when he appeared, the council again postponed judgment for twelve months. Dr. Robertson now appeared, and Mr. S. Winterbotham, of Messrs. Waterhouse and Co., solicitors to the council, read a statement by him that he had been in Bethlem Hospital as a patient and had been unable to obtain employment. The President asked him whether he was at the moment under the influence of alcohol; this he denied, saying that he had last taken alcohol in August. The council directed the registrar to erase his name from the Medical Register.

DRUNKENNESS: JUDGMENT POSTPONED

William Francis Hirsch Coulthard, registered as of Balwinnam, Aspatria, Carlisle, M.B. Edin. (1927), appeared before the council accompanied by Mr. H. G. Peacock, ounsel, instructed by Messrs. Le Brasseur and Oakley, olicitors, for the London and Counties Medical Protection Society. The council found that he had twice in the present year been convicted before petty sessions of drunkenness, on one of these occasions in charge of a motor-car; that under the influence of drink he had used obscene language and assaulted a patient; and hat he had twice in the present year requisitioned four ampoules of 'Myocrisin' at the expense of the Cumberand County Council by falsely representing that it would be administered to a patient, whereas none of it was administered to her. Mr. Gerald Howard, counsel, prosecuted, instructed by the council's solicitors. Counsel for Dr. Coulthard admitted that the offences had all been due to excessive drinking but maintained that he doctor had since the last conviction been a total abstainer and intended to remain so. Dr. Coulthard confirmed this resolve in evidence. He said that he had n fact been treating the last patient with myocrisin for four years, and that after she had ceased to be his patient he had inadvertently continued to sign requisition forms. He had not used the supplies.

The President announced that in view of Dr. Coulthard's assurances of abstinence the council would postpone udgment for two years.

Reuben Denny, registered as of 64, Twyford Avenue, Acton, London, W.3, L.R.C.P.E. (1929), had been convicted in May, 1946, at Marlborough Street, of driving a motor-car under the influence of drink. He admitted an earlier charge in 1938, for which he had appeared before the council. He said he had not been practising at the time of the recent charge; his health had broken down owing to head injuries, for which he had been sent home from Gibraltar. The council postponed judgment for one year.

Mrs. *Ethel Grundy Toward*, registered as of Brookside, Durham Road, Birtley, Co. Durham, M.B. Durh. (1925), appeared after two convictions before the Gateshead magistrates, one in September, 1945, and the other in February, 1946, of driving a motor-car under the influence of drink. She was accompanied by Mr. Peacock, instructed by the solicitors of the London and Counties Medical Protection Society. She said that she practised in partnership with her husband and had succumbed to alcoholism through overwork, as she had had to run the house in addition to her practice. She had been successfully treated in a home. In the belief that her present appearance would be a warning to her, the council decided that her name should not be erased.

CASES ADJOURNED FROM PREVIOUS SESSIONS

Anthony John Watkin, registered as of 11, Woodville Road, Newport, Mon, B.M. Oxfd (1943), had been convicted of attempted abortion and bound over. In November, 1944, the council postponed judgment. He now appeared and presented testimonials. The council decided not to order the erasure of his name.

John Corboy, registered as of Freshfield, Lon Dervis, Tycoch, Swansea, M.B. N.U.I. (1939), had been twice convicted in 1945 of being drunk in charge of a motor-car. Last November the council postponed judgment for one year. In view of satisfactory evidence of his character and conduct the council decided not to order the erasure of his name.

William Allan, registered as of 31, Hill Crest, Burnley Road, Sowerby Bridge, Yorks, M.B. Glasg. (1920), had been imprisoned for three months for obtaining £5 by false pretences. In February this year the President announced that the conviction had been proved to the council's satisfaction, and added that from the council's point of view Dr. Allan's record, both as regards his financial dealings and drink, was not satisfactory. The council postponed judgment for two years but desired to see him at intervals during that period. Dr. Allan now appeared and produced testimonials. He admitted that he took a drink on odd occasions but was deriving benefit from psychotherapy. The President said that the council desired to see him again at its session in May, and hoped that he would then produce better evidence of his character and conduct.

British Pharmacopœia

Prof. DAVID CAMPBELL, presenting the report of the Pharmacopœia Committee and Commission, said that the whole text of the new *British Pharmacopœia* had been sent to the printers and a part had been returned in proof. While, however, the commission recognised the desirability of producing a new and complete pharmacopœia as soon as possible so as to relieve pharmacists and manufacturers of the necessity of consulting numerous addenda, it regretted that it could not yet suggest a date for the appearance of the new edition.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED NOV. 23

Notifications.—Smallpox, 0; scarlet fever, 1402; whooping-cough, 1773; diphtheria, 319; paratyphoid, 20; typhoid, 3; measles (excluding rubella), 5428; pneumonia (primary or influenzal), 708; cerebrospinal fever, 43; poliomyelitis, 16; polioencephalitis, 0; encephalitis lethargica, 2; dysentery, 69; puerperal pyrexia, 124; ophthalmia neonatorum, 61. No case of cholera, plague, or typhus was notified during the week.

The number of Service and civilian sick in the Infectious Hospitals of the London County Council on Nov. 20 was 959. During the previous week the following cases were admitted: scarlet fever, 46; diphtheria, 19; measles, 16; whooping-cough, 27.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 1 (0) from measles, 11 (0) from whooping-cough, 5 (0) from diphtheria, 64 (10) from diarrhœa and enteritis under two years, and 18 (3) from influenza. The figures in parentheses are those for London itself.

Sheffield reported the fatal case of an enteric fever. Liverpool had 4 deaths from whooping-cough. There were 11 deaths from diarrhœa and enteritis at Liverpool and 8 at Manchester.

The number of stillbirths notified during the week was 294 (corresponding to a rate of 32 per thousand total births), including 38 in London.

On Active Service

AWARDS

THE following awards have been made for gallant and distinguished service while engaged in special operations in South East Asia.

M.B.E.

Major J. G. DUMOULIN, M.B. Lond., R.A.M.C.
Captain E. J. HARRISON, M.B. Camb., R.A.M.C.
Major ARRON RAPOPORT, L.R.C.P.E., R.A.M.C.

CASUALTY

DIED

Captain JAMES WALSH LILLICO, M.R.C.S., I.M.S.

The death is announced of Captain Lillico, in October, 1942, while a prisoner-of-war in Japanese hands. After taking the Conjoint qualification in 1937 he joined the Indian Medical Service. He leaves a widow and a son.

assisted some voluntary bodies in work of this kind—notably the Lord Roberts Memorial Workshops. Local authorities will continue to be responsible for the blind, but the Ministry will help the workshops financially. In Scotland the Ministry will take over the responsibility for training in workshops of all blind people over the age of 18.

The Disabled Persons Employment Corporation Ltd., under the chairmanship of Viscount Portal, will develop employment facilities for the severely disabled wherever there is need of them. A programme of 50 factories, to be called "Remploy Factories," for this purpose has been approved, and the first three of these factories are now in action. People pensionably disabled as a result of service in the recent war may be helped to set up in work on their own account if this is considered the best form of resettlement for them.

Two hostels for paraplegics, each catering for 50–70 people, are to be built, one in the London, and one in the Glasgow, area. Meanwhile the Ministry of Pensions has opened convalescent wards at Stoke Mandeville Hospital, where prevocational training is offered. A settlement for these patients is being established at Lyme Green Hall by the joint committee for Cheshire of the British Red Cross and Order of St. John, and the British Legion is undertaking to adapt the patients' homes to their needs. "They are for the town's end, to beg during life," said Falstaff of the old soldiers. Here at least we can admit to a little progress.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

DISCUSSION OF THE ACT

THE position which has arisen from the enactment of the National Health Service Bill was discussed at a meeting of fellows on Nov. 29. Sir **ALFRED WEBB-JOHNSON**, the president, said that the college's representatives had done their best to consider the National Health Service in a non-political way; the freedom of the profession was regarded not as a vested interest of the profession but as guaranteeing the freedom of individuals to be served as they pleased. The college had supported the Negotiating Committee because it represented the whole profession: in such a question as this the whole profession should stand together, and the college should support the general practitioner. Despite representations, several important principles to which objection was taken had not been removed from the statute. Ownership of practices might seem a guarantee of independence and devoted service, yet their sale and purchase was to be prohibited. But here opinion was divided, and the point was perhaps not worthy of the important category in which it had been placed; it might possibly be settled by negotiation. In the restriction on the place where the general practitioner might work, the only concession had been that the decision should rest with general practitioners already employed in the area. Other objectionable features were the proposed tribunals with no appeal beyond the Minister, and the threat of part-payment by salary. But "I do not find in any of these items sufficient grounds for refusing to discuss the implementation of the Act with the Minister." The most undesirable of them was the salary element, which might interfere with the doctor-patient relationship.

For specialists, the Act created a monopoly of hospital services; but by negotiation it might be possible to get regulations framed so as to leave the profession as free as it is now. The council agreed that in a large proportion of hospital pay-blocks charges should be controlled; but in some part there must be a free relationship between doctor and patient. The powers given to the Minister might impede private venture; he could, for example, take over a private clinic. What was important was to preserve independent practice. Considerable concessions had been won; and further concessions, the President believed, might be obtained in framing the regulations. The council as a body favoured the profession's support in this work; it was for individuals to make up their own minds.

Mr. **WILFRID ADAMS** said that the Act was ill-founded because the profession had not been invited to lay down the form of the new service.

Mr. **LAWRENCE ABEL** agreed that there must be a medical service for all. But he was opposed to negotiation over regulations, because the Socialist Party's declared aim was a whole-time salaried service. The patient's main safeguard, he suggested, lay in the doctor having bought his share in a practice. The Act allowed for consultation with the profession, but the profession's advice would not necessarily be accepted. The most important item was the State-ownership of hospitals, by which a monopoly would be created. By a slight amending Act the service could be founded on rock.

Mr. **W. ETHERINGTON-WILSON** said that the feeling was growing among general practitioners that the people most likely to let the profession down were the consultants and specialists. Shackles, dictatorship, or direction must sooner or later appear whatever the Minister said now.

Mr. **REGINALD PAYNE** was opposed to this fresh example of delegated legislation, and monopoly without the right to dissent. The student was to be rendered servile, mobile, and docile. In ten years half the council would be civil servants and the other half Government pensioners. He saw the National Health Service as a whip in the hand of the executive.

Mr. **J. S. HORN** said that points of principle should not be confused with points of expediency. No mention had been made at the meeting of doctors' economic position under the Act, since that would be an admission tha some of the opposition was based on self-interest. Th Act should be seen as a democratic measure put forwar as the result of a general election at which the plan ha been laid before the electorate.

Mr. **A. DICKSON WRIGHT** held that a free choice o hospitals is as important as a free choice of genera practitioners; there was nothing wrong with the volun tary hospitals or their finances. Where commercia organisations were nationalised, dissident elements coul be condemned to prison or the peerage; here the Govern ment had to deal with no board of directors, and al that doctors needed to say was that they were not goin to work the Act.

Mr. **SANGSTER SIMMONDS** said that the nature of the service would depend on how doctors did their work: voluntary hospitals had been successful because doctors had worked well. Most of the criticisms had been against points to be settled by regulation, and further improvements might be obtained if the profession negotiated.

A motion regretting the council's decision in favour of discussing regulations (see p. 854) was not voted on. The meeting agreed, without a formal motion, that the main body of the profession should be supported in its decision by the college.

GENERAL MEDICAL COUNCIL

WINTER SESSION, NOV. 26—28

AFTER the President's address, reported last week, Dr. **ROBERT WILLIAM CRAIG** was introduced as direct representative for Scotland.

The names of *James Jackson Brown*, *Erich Hohenberg*, *Arthur Patrick Kennedy*, *Matthew Morgan-Daley*, *Brendan O'Carroll*, and *Archibald Walker* were restored to the Medical Register, and the names of *Harry Ernest Best* and *Alfred Horace Myring* to the Dentists Register.

Penal Cases

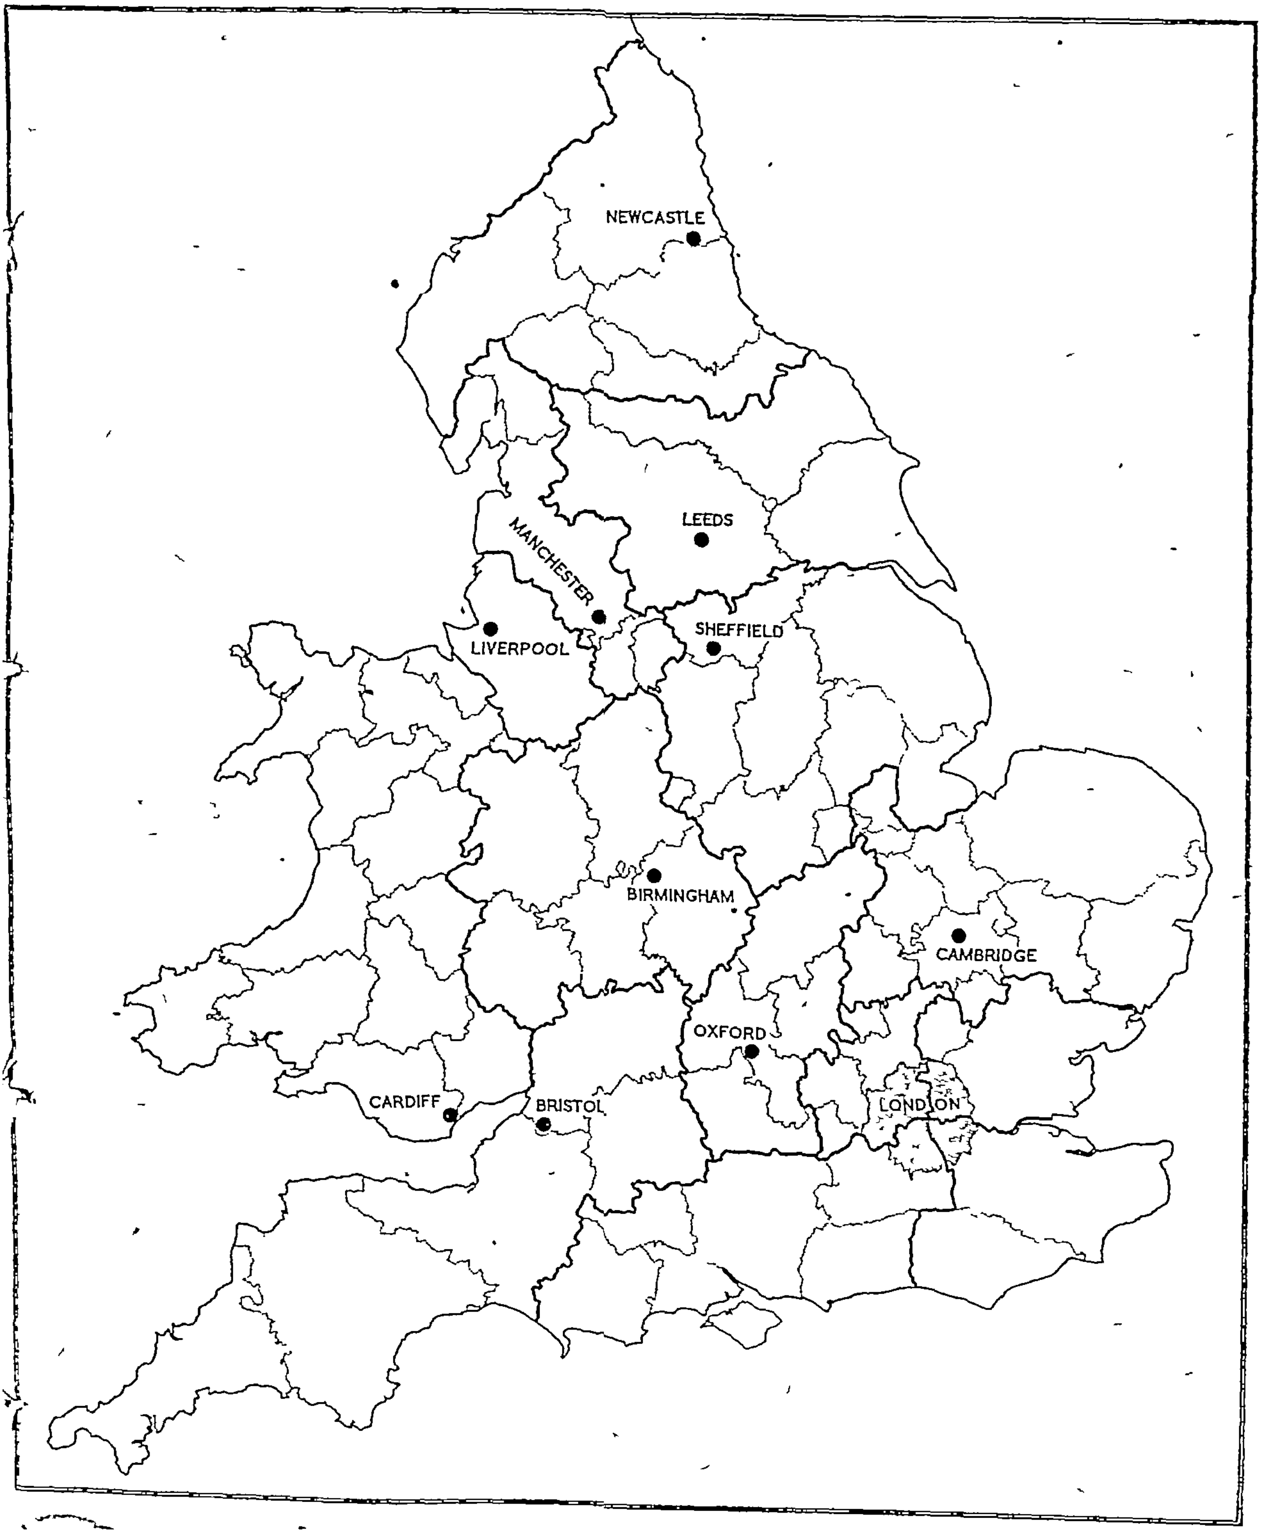
On the recommendation of the Dental Board, the council ordered the erasure from the Dentists Register of the name of *Ascott William Harris*, registered as of 29, John Bright Street, Birmingham, 1 (Dentists Act, 1921), for associating in practice with an unregistered person who advertised in Birmingham newspapers a hospital for broken dentures; and the name of *George William Southwood Clark*, registered as of 94, West Street, Gateshead, 8 (Dentists Act, 1921), who had been sentenced to hard labour at Northumberland quarter sessions for breaking and entering a house and stealing goods. Mr. Clark had written a letter to the council stating that he had practised as a dentist for forty years and was entirely innocent of the offence.

ERASURE FROM THE MEDICAL REGISTER

Graham George Robertson, registered as of 25, Mariners Lane, Tynemouth, M.B. Edin (1934), had appeared before course be accessible as at present to the inhabitants of other regions, and its university influence could be exercised on these regions as effectively perhaps as under the Government scheme: the University of London would be represented on their boards, and two or more teaching hospitals would adopt each of them.

SENTIMENT ?

These are some of the questions raised by the Minister's proposals, on which he invites comment by Dec. 15. Local authorities with large hospital services which will be divided or fragmented by the proposed boundaries may feel that too much emphasis has been placed on the potential rôle of the universities, and too little on the maintenance of going concerns. Again, those who want to see the universities and medical schools in a key position will not necessarily be convinced that the key position must be geographically inside the region—nor that London is the only university capable of interesting itself in more than one region.



Reconstruction

THE MINISTER'S REGIONS

SOME CRITICISMS AND ALTERNATIVES

FORMERLY it was intended that for hospital purposes England and Wales should be divided into about 30 regions. The white-paper issued when the National Health Service Bill was introduced spoke of 16–20. But in the Government's draft scheme (summarised in our last issue and illustrated in the accompanying maps) the number is reduced to 14. Of these, 4 are so big that they will have to be subdivided, the regional board delegating many of its functions to a committee responsible for part of its area.

In coming down on the side of large regions the Ministry of Health has gone far to meet the "voluntary hospitals" view. On the face of it, the bigger the region which a hospital board covers, the less likely it is to attempt detailed control of individual institutions, and the more it will leave to the hospital management committees. The function of the boards, as the Minister now sees them, is the planning, coördination, and provision of hospital and specialist services rather than the control and management of hospitals, and his plan suggests that the management committees are to have the responsibility and powers they need to attract able men and women to their work.

There are some, however, who, remembering the difficulty of coördinating the activities of voluntary hospitals, fear that any high degree of autonomy for the management committees will prevent the regional board from organising a coherent hospital service. Such a service, they believe, demands more than regional planning and regional coördination : to be effective the board must be able to close, amalgamate, and expand hospitals, to build new ones, to apportion funds, to arrange the bulk purchase of supplies, and to control staff appointments and discipline. They say that if boards are too weak, and management committees too strong, the anarchy of the old voluntary system will begin all over again.

The case for having 30 or more regions, with relatively strong boards, was set out by a *Times* special correspondent on July 12.

> "However regarded," he said, "a regional hospital service will be a large undertaking, especially since it is to be directed by a board of part-time and unpaid members, all of whom will have many other duties to occupy their time, including earning their daily bread. If they are to take their hospital board duties seriously, occasional meetings of the full board will not suffice. Much of the work will have to be done through committees, of which at least five—for finance, staff, planning and general purposes, supplies and equipment, and establishment or building—appear to be necessary: and some of these committees will undoubtedly require subcommittees for special subjects, such as mental health services, tuberculosis, and radiotherapy.
>
> "The larger the regions the heavier will be the burden falling on each board, and the greater the time spent by its members on travelling to meetings."

Excessive strain on the members of the board would, he thought, prevent the development of a human and personal service: so far from promoting self-government by the hospitals it might lead to stifling of local initiative through excess of rules and regulations. However this may be, it is clear that infrequent meetings of the board and small attendance at its committees would mean that much of the work would be left to the chairman and the paid staff, and this might favour bureaucratic technique.

Finally objection is raised to the Minister's scheme on the ground that his 14 regions do not take enough account of "natural hospital areas" but are based primarily on the geographical situation of the universities. Their design starts from the assumption that every region must have a university within its borders; and not all the universities happen to be conveniently situated.

UNIVERSITY AND REGION

The choice of a university town as the capital of each region is to many people one of the most attractive features of the scheme. Admittedly the universities and their medical schools have hitherto had little to do with some of the most important parts of the hospital services, such as the provision for infectious diseases, mental disorder, or the chronic sick; and it would of course be a mistake to give them a predominance that would drive out valuable experience of such work. Nevertheless it is easy to see that in the new hospital and specialist services the universities might make the vital difference between mediocrity and excellence, not only because they can insist on scientific and professional standards but because they can offer the incentive o academic status to hospitals and staffs which study to deserve it.

In the *Times* of July 15 Lord Moran pointed out that in future provision must be made for postgraduate teaching for "the whole profession in relays," and this must be undertaken by hospitals not as yet seriously concerned with teaching.

> "The particular task of the universities," he said, "would be to see that hospitals in the regions which have been chosen to teach post-graduates are qualified to do so by the competence of their staff and by the nature of their equipment. Each university must demand that every teacher in its region is recognised and approved by its medical faculty, just as all those who now teach in the 12 medical schools of London have to apply to the London University for recognition. In that fashion the faculty will ultimately be largely responsible for the quality of the staffs and in consequence for the efficiency of all sizeable hospitals outside the special 'teaching group.'"

But even those most anxious to promote university influence in the regions do not all accept this as an argument for having only about 14 regions, each with a university inside it. If there were 30 regions it would be possible for each university to adopt two or more in its neighbourhood; for it is not essential that the university should be geographically within the region it is to influence.

This particular argument has been put forward cogently in relation to London.

LONDON

In the Ministry's scheme, London is divided into four parts which form the proximal ends of four large regions, one of which stretches to Portland Bill. The division has been made in such a way that each part contains at least two of the dozen undergraduate medical schools at present existing in the metropolis. All four regions will have the advantage of a share in the many important medical institutions of London, whose hospital service is far better developed than that of most of the home counties, and the inhabitants of distal areas will stand to gain immediately by sharing equally with Londoners. On the other hand, it may be argued that in each case the London end of the region will be the *tail* which wags the dog, and the effect of this will be to prevent the development of self-sufficient hospital services which the peripheral areas could and should build up. How big a part will Canterbury, Brighton, and Maidstone really play in the affairs of a region that includes a quarter of London ?

An alternative scheme which has found some support is that London itself, which has historic and functional unity, should not be artificially cut in pieces but should form a region of its own. Its hospital beds would of

In England Now

A Running Commentary by Peripatetic Correspondents

DOWN here in Brighton we have been having a pre-view of a play dealing with the keen young doctor and his imaginary frustrations by the State Medical Service. Written by Warren Chetham Strode, author of *The Guineapig*, it is called *The Gleam*, though possibly *The Glow-worm* might have more aptly described the mentally conflicted hero, poor "Dr. Alan Boyd, F.R.C.S." Boyd is a young G.P., so we will not cavil at his courtesy title. If some may feel a trifle uncomfortable during his oration on our Vocation ("hands off healing," &c.) it does not spoil the evening's fun, and one is relieved that he had this psychological catharsis; it must have expelled many vapours—which we had noticed with sympathy.

The play goes to London this week. Meanwhile my own views, if I may express them without presumption, are:

(1) That "vocation" applies to firemen much more than to the senior G.P., who usually, though not by any means always, is very cosy and uses his own shining conveyance which he does not have to clean himself.

(2) That the *lay* members of committees and boards are much more frightened of doctors than we are of them. Whereas, on the other hand, the medical members can be quite dangerous and oppressive.

The type I most fear is the retired army A.D.M.S. equipped with a Diploma in Medical Administration and Social Coöperation. This is the bird who will make young Tim Cartwright afraid to open his official correspondence. The problem of the medical repercussive punitive poster, armed with higher authority, should now, in good time before appointments are made, be treated as urgent.

* * *

I find all this chat about the conservative treatment of perforated ulcer most interesting. Having read the original articles and the subsequent correspondence and resisted the temptation of writing myself to describe the case I once had when, three days after the calculated perforation, I was able to elicit a hitherto unrecorded physical sign—namely, shifting resonance in the peritoneal cavity, owing to the escaped gas which had not then been reabsorbed: having got as far as that, my next course was clearly to await the advent of the Right Case.

Yesterday he arrived. Forty-five, three years' dyspepsia, two hours perforated, nothing to eat since the night before, and (to discourage the narcologist) rather a poor chest. All the physical signs were there except absent liver dullness and after all it was early days for that. Two other colleagues agreed that no better case could be found—and at that exact moment my Guardian Angel gave me a prod in the ribs and told me I had better open him up. After I had removed the gangrenous appendix I said to him (my Angel, that is) shall I write to THE LANCET about this? If you do, said he, someone will only write back and say, "Well of course if the poor fool can't diagnose an appendix . . ." So that's how the matter rests. The other chaps can work out the statistics and explain things to the Coroner from time to time. Like Lord Vansittart I can say with feeling: "Never again."

* * *

I called on a very deaf lady one day. At the top of my voice I tried to persuade her that I was not looking for lodgings, but we made no progress. Then with a flash of inspiration I placed my stethoscope in my ears and was relieved to see understanding dawn in her eyes. "Ah, that's bad," she said. "Be you as deaf as I?"

* * *

An extract from a recent speech:

"I look forward to the time when some party in power, or perhaps some party seeking office, becomes gravely concerned about the spiritual health of the nation, and devises a comprehensive scheme of salvation at ninepence a week for men and sevenpence for women and children. With free choice of parson. . . .

"The clerical profession will be expected, indeed will be instructed, to prevent sin; and if any member fail to bring a sinner to repentance within a reasonable time—say three months—an inspector will be sent along to look into the case. . . .

"Much of the clergyman's time will be spent in making returns, rendering reports, issuing certificates of pardons and indulgences, and filling up the counterfoils. He will in fact once again become a clerk in Holy Orders, but controlled by a layman, who in a previous government was Postmaster-General or Agriculture and Fisheries together with his whacking big administration in Whitehall. . . .

"I say I am looking forward to this, but I am afraid that it is only a fantasy. Somehow I don't think the churches would allow it to come to pass."

* * *

The Medical Exhibition—not perhaps in its old glory, but nevertheless itself, with its free literature, its gentlemanly barkers, among whom the profession go about seedily, trying not to look shamefast at the bulging of their pockets with pharmaceutical baksheesh, its striking similarity to the pre-war Schoolboys' Exhibition, where small boys goggled at the interior of radio sets and guns exactly as we goggle at electrocardiographs and shock-boxes.

Like the B.B.C., it has its three intellectual levels. The highbrows converse with the experienced technicians of Messrs. X and Y or ask awkward questions about one-sweep time-bases and square waves (what fun the radar pundits can have at the expense of the uninitiated—before the war few could rag the oscillograph-makers on their own subject); the middlebrows study bags and baby food; the lowbrows go in for silver pills and polypharmacy. And all of them surreptitiously collect samples. So did I, apologetically. "You shouldn't worry," said the barker, "one of 'em's brought a ruddy great portmanteau." Then there is a certain palatable laxative, which incidentally makes a marvellous cake-decoration. I was sorry for the lonely little woman demonstrating surgical belts, to whom nobody talked. How she must have wished for one of the oscillographs, to show how your belly goes in and out when you wear them!

I do not know where our pharmaceutical colleagues recruit their barkers; it's a hazardous life. They have no means of knowing if the little man who is trying to viva them is a student or a regius professor. The first few answers you get are always ranging-shots, yet only one of the salesmen examined by me would have failed, and only he because he told me that a pill, made largely of œstrogens, would be suitable for children under five. The oscillographers let you twiddle their knobs with an air of deference and one hand ready to make a grab if you look like blowing out the tube. The samples, too—some are bottles of 100, others, pretty enough for a doll's house, have the label arranged so that you can't count the pills; the sternest merchants put three chaste tablets in a little 'Cellophane' bag, and if you don't like it you can leave it. I often wonder what people do with them. I know one colleague who makes toy chemists' shops for his nephews. In any case, it is unwise to go without a poacher's pocket. Full of diabetic chocolate, and bulging with calves-foot jelly, I went home resolved to go next year, and assured that somebody at any rate will send me some parcels this Christmas.

* * *

F. D. R.

A statue in a London square? The choice
was made for those unborn—to come and stare
or "Roosevelt's statue? Yes, I'll meet you there."
For us who heard, for ever he's a voice
that pierced the black-out for a friendly chat—
so decent of him to drop in and show
the neighbours what he felt, what now they know—
a voice that told of tools and ships and dawn, and this
and that.

But will it show the wasted limb or shun
so sad a showing in a London square
with lapidary robes? Or shall men stare,
"D'you see the contrast? Yes? that's where one war
was won."

The advocates of smaller regions can point to the difficulty of giving life to a regional authority which is too remote to command local interest or evoke local patriotism. And in Wales at least they can point to a region where natural hospital areas have been ignored for extraneous and sentimental reasons.

Against these objections, which are undoubtedly valid, the Ministry can marshal arguments in favour of its plan. On the level of practical politics 14 boards present less difficulty, in appointment and staffing, than 30. On the level of intangibles there can be little doubt that the large region commanding whole attention of the university which served its intellectual capital would have more prestige personality than the small which shared with others attention of a university outside its borders. The smaller the region the more the probability that it will always be merely unit in a national service. Th larger the regions the more chanc we shall have of developing federation of regional medica services, each with a characte of its own and striving to prov its worth. This desira development would be favour if the regions chose individu names, such as Tyneland, Wesse and Westland, and if all th services coming under th regional board were called th Tyneland, Wessex, or Westlan Hospital Service.

With improving communications, local patriotism and interes may be expected to exten further, and might well attac themselves to a service whic explicitly belonged to the region, instead of being just part of an organisation as national as the Post Office.

But if local sentiment is important, what about London? Can it really be wise to begin by splitting the capital city arbitrarily into four zones?

rapidly fatal, the true diagnosis may be missed, unless a necropsy and elaborate hæmatological investigations are done.

A boy, aged 6 years, was admitted to hospital following a convulsive attack. He was very ill, pyrexial, and drowsy. The same evening his temperature rose to 105° F, while no satisfactory explanation could be found on clinical examination. In view of the seriousness of his condition, sulphapyridine was given. During the next few days blood-counts revealed a marked fall in the total of white blood cells, with granulopenia. On one occasion the white-cell count was 1140 per c.mm., with 400 granulocytes per c.mm. A tentative diagnosis of agranulocytosis due to sulphapyridine was made, and the child was treated accordingly. A blood-transfusion of four pints improved his condition so much that he was discharged home a month later, apparently cured. He was seen by me again about a year later for a swelling of the right testicle, and the unfortunate child was found to be suffering from lymphatic leukæmia. Death followed rapidly, and the diagnosis was confirmed by post-mortem examination.

St. Charles' Hospital, London, W.10. A. F. SUCHECKI.

GONORRHŒA IN THE FEMALE

SIR,—Dr. Neville Mascall (Nov. 16) has put forward a timely plea for care in the use of penicillin, and particularly for full and repeated tests after its administration for gonorrhœa in the female.

As he says, gonorrhœa in women is almost always complicated by the presence of other infecting organisms, and even the complete elimination of gonococci is not synonymous with "cure." It is therefore necessary that specific treatment with sulphonamides or penicillin should be supplemented—usually by some form of local treatment.

What advantages has penicillin to offer? At best it can render the patient non-infective in 12–24 hours; with sulphonamides, as usually given in an outpatient clinic, non-infectivity may be achieved in from 3 to 5 days. With sulphonamides there may thus be a lag of 4½ days, and it would be interesting to know what proportion of patients would be likely to risk infecting others during this time if they were told the diagnosis and its implications. With penicillin treatment observation must be continued for about six months, owing to the risk of its masking or delaying the early signs of coincident syphilis; and with the increased incidence of syphilis such double infections are more frequent now than in the years before the war.

A young married woman was treated with penicillin for gonorrhœa in pregnancy; after delivery sores developed and the Wassermann reaction became positive; the baby also was found to have a strongly positive Wassermann. Reinfection of the mother was virtually ruled out.

It needs very few cases of this sort to counterbalance the problematical gain to the public health of a few days' less infectivity by using penicillin. Up to now the success-rate of penicillin in acute gonorrhœa has been reported to be 90–100%; but if results similar to Dr. Mascall's are obtained by other authorities, then the scale will begin to come down heavily against this treatment.

Experience at the Royal Free Hospital clinic has proved that, with rigid methods of administration, failure to respond to sulphonamides is rare. Advantage is taken of the daily attendance for local treatment in the early stages to combat the incapacity of patients to take the necessary regular doses of sulphonamide. Each patient is given only one day's supply at a time, and each day emphasis is laid on the necessity for taking it according to the instructions on a simple typed slip. Penicillin is given only where the condition does not respond to sulphonamides, or in exceptional circumstances in adults; experience with penicillin in the treatment of gonococcal vulvovaginitis in children accords with that of Dr. Mascall.

In the older textbooks on venereal diseases the authors were often content to say of treatment in the female that it was carried out on the same lines as in the male. Perhaps the disappointing results with penicillin will emphasise that the condition is fundamentally different in the two sexes.

Royal Free Hospital, London. MARY MICHAEL-SHAW
Director, V.D. Clinic.

TREATMENT OF ANURIA

SIR,—With reference to the article by Mr. Reid and others (Nov. 23) the following case may be of interest.

A staff-sergeant fell out of a window in Beirut in November, 1945, sustaining multiple injuries including a simple fracture of the right femur at the junction of the middle and upper thirds. He was treated in a slung Thomas splint in abduction with skeletal traction by means of a Kirschner wire through the tibial tuberosity. Leaving Beirut that month I lost sight of this patient until January, 1946, when I encountered him again in Palestine. At that time there was neither clinical nor radiological evidence of any union whatsoever. He had fully recovered from his other injuries, which were comparatively trivial. The diagnosis of delayed union due to the interposition of soft parts was made.

His general condition appeared to be normal, and open reduction of the fracture and internal fixation was decided on. The operation was performed under general anæsthesia without a tourniquet. The diagnosis was confirmed and the fracture reduced and fixed internally by means of a Lane's plate and six screws. After skin closure and during the application of the plaster hip-spica the patient collapsed and it was decided to transfuse him with blood. He had lost quite an appreciable amount during the operation. Cross-agglutination tests were carried out and he was transfused with two pints of citrated group O4 blood. The first pint was run in rapidly and the second pint continued while he was recovering from the anæsthetic. His condition improved and everybody was satisfied until the next morning when it was noticed that both his conjunctivæ were deeply jaundiced.

The transfusion was immediately suspect and the two donors having been traced were recalled and further typings and cross-agglutination tests were carried out. These confirmed that both the donors were group O4 and that no agglutination took place with the recipient's blood. The blood when transfused was 14 days old and had been kept in a refrigerator. No sign of lysis to naked-eye tests had been reported by the blood-transfusion officer before it was given.

The patient presented a very grave picture, with a deepening jaundice, hæmoglobin 40%, and an oliguria amounting to two ounces of very deeply stained urine containing large numbers of red blood cells and casts. The case was seen in consultation with Lieut.-Colonel R. H. Dobbs, R.A.M.C., and it was decided not to try to produce a diuresis by the administration of large amounts of fluids intravenously. The object was to balance input and output and to infuse alkalis and hypertonic glucose. Three or four pints of fluid were given intravenously daily in addition to the fluids he retained by mouth.

In spite of these measures the patient's condition worsened: no urine was passed normally, but two ounces was withdrawn daily from the bladder by catheter. Daily blood-urea estimations had shown the amount to be rising by approximately 50 mg. per 100 c.cm. a day. On the eighth day after the original operation the patient's condition seemed critical. He was still vomiting four or five times a day, the oliguria at two ounces daily, and the appearance and the constituents of the urine remained unaltered. The blood-urea now stood at 400 mg. per 100 c.cm. and the hæmoglobin was 40%, but at no time was there any evidence of œdema.

After consultation with civilian colleagues who had had at that time some experience of peritoneal dialysis it was decided to perform a renal decapsulation. The hip-spica was removed (the thigh incision had healed), and the area was prepared for operation. This was conducted under spinal 'Percaine' anæsthesia. The right kidney was exposed and the findings on incising the capsule were similar to those described by Mr. Reid. Decapsulation was performed on the right side only and the wound drained by means of a corrugated rubber drain.

The subsequent progress was extremely interesting. From the day after the decapsulation increasing amounts of urine were passed daily with an increasing concentration of urine urea. The blood-urea however continued to rise until the fifth or sixth postoperative day, when the figure stood at 600 mg. per 100 c.cm.; the maximum diuresis was also obtained at about this period and thereafter with a steadily increasing urine urea the figure fell steadily. On the eighth day, just as the picture had begun to improve, a further crisis arose. The hæmoglobin had fallen to 20% owing to the formation of a moderate-sized hæmatoma in the renal wound. With a great deal of trepidation a further transfusion of two pints of blood was given, without any general or local reaction.

Letters to the Editor

THE REGIONAL BOARDS

SIR,—Many believe that the regional board will make or mar the future National Health Service. We have been interested to read the views of distinguished members of the medical profession as to how the regional boards might be constituted and administered, and we earnestly hope that Sir Leonard Parsons and Sir Ernest Rock Carling are right in assuming that the primary function of the regional board will be to organise and coördinate a hospital and specialist service which will provide the best possible facilities for the patients in the region. We do not, however, view with equanimity the suggestion of the former that the primary qualification of the chief executive officer should be his "intimate knowledge of the medical aspects of hospital care."

The regional board is not intended to interfere with the medical aspects of hospital care, which responsibility will, we hope, remain with the medical committee of the individual hospital. There is, however, a real danger of this happening by the overweighting of academic and medical representation on the regional board.

I doubt whether many really appreciate the enormous magnitude of the administrative task of these boards, and the great responsibility which rests with them in planning and thereafter supervising their vast hospital service. One of the most urgent duties will be to provide additional beds, and to stimulate recruitment of adequate nursing, domestic, and ancillary staff. The board is also responsible under the Act for the maintenance of existing hospital buildings, their equipment, furniture, and other movable property, and for the proper accounting of moneys granted by Parliament and disbursed to the hospitals in its region. It is obvious that much of the board's work will have to be done through committees and subcommittees.

The members of the regional board are part-time and unpaid. Let us be sure, therefore, that the chief executive officer is one with sound and wide experience of the administration of hospital services. He should be so equipped as to be able to interpret with knowledge the diverse interests of this vast regional organisation, and be without bias in the advice which he gives to his board upon the purely medical aspects of hospital care. In other words, there should be expert technical advice on tap and not on top.

Westminster Hospital,
London, S.W.1.

CHARLES M. POWER
House Governor and Secretary.

CORONARY OCCLUSION

SIR,—Dr. Maurice Newman's review of 50 cases of coronary occlusion in young adults (*Lancet*, Sept. 21, p. 409) and Sir Maurice Cassidy's Harveian oration (*Lancet*, Oct. 26, p. 587) prompt us to send you the following observations from our experience in Vienna during recent years.

Sex-incidence.—In 16 cases of coronary thrombosis occurring between 23 and 40 years of age there were only 3 women; while in a collection of 521 cases of all ages which one of us made from the literature, 81% were in men and 19% in women.[1]

Predisposing Factors.—The patient is typically tall and more developed in length than breadth with a never-tiring "vegetative hypertensive" temperament. Focal infection is common. Most cases have tonsillitis and dental granulomata, which we always treat after the infarct has healed. Physical strain, in our experience, is a rare cause and no strict time relationship can be established. We consider that tobacco in excess is a predisposing, and may even be a precipitating, cause. Syphilis is rarely even a possible factor; only 4% of our cases had positive Wassermann reactions. The significance of hypertension as an ætiological factor is difficult to assess, since the blood-pressure is lowered after the attack and information about the pressure before the occlusion is usually lacking.

Onset of Symptoms.—Careful history-taking shows that coronary thrombosis is not "a bolt from the blue"; all patients in our series had prodromal symptoms. Almost always these consisted in a sensation of precordial pressure of varying strength during physical exertion and excitement; the distribution may be circumscribed or diffuse.

Physical Findings.—Lewis[2] noted that the collapse in coronary occlusion resembled vasovagal syncope. We have studied 51 cases of acute cardiac infarction admitted to hospital within eight weeks of their first attack of pain.[3] Apart from persistent bradycardia attributable to a lesion of the right coronary artery, a temporary slowing of the pulse occurred in 15 cases. Electrocardiography showed this to be variously associated with auriculoventricular block, auriculoventricular nodal rhythm, sinus bradycardia, or simple sinus arrythmia. We describe a definite bradycardial phase (which we call phase I), with general flaccidity, low blood-pressure, bradycardia, and stupor; the electrocardiogram is characterised by wide high waves, the Q–T interval being at or above the upper limit of normal. We assume this condition to be due to an inhibiting, cardiogenic, vasovagal reflex[4]—a protective mechanism for the acutely diseased heart. This is followed by phase II, with a gradual or sudden onset of motor restlessness and tachycardia, which is certainly not protective and which is probably induced by th release of abnormal metabolites from the damag *myocardium.*

Diagnostically and prognostically we consider t recognition of substernal or parasternal discomfort oppression in young people to be most importa Electrocardiographic records may be valuable, especia when they are made under working stress. We ha also used our recently developed methods of investigati the dynamics of the heart by "rheocardiography."[5]

SULPHONAMIDE GRANULOPENIA IN CHILDRE

SIR,—Your annotation of Oct. 26 does not, I thi sufficiently emphasise that while mild sulphonam granulopenia is fairly frequent in children, true agranu cytosis is very rare, especially with the less toxic mode compounds.

The benign form of granulopenia, or rather neut penia, disappears spontaneously when administration stopped, and no other measures would seem necessa Although it has become almost traditional to administ large doses of pentose nucleotide, its curative power very questionable, and it has often proved complete useless.

True agranulocytosis following sulpha drugs is a ve serious, but luckily rare, complication. Several clinicia have recently drawn attention to the value of penicill in preventing and combating the infection which cont butes to the fatal outcome of secondary agranulocytos In my opinion much more emphasis should be laid on t beneficial effects of whole-blood transfusion; it is present our most reliable weapon. In assessing t results obtained with folic acid and pyridoxine, it is w to remember that similar satisfactory results have bee claimed for nicotinic acid and various liver preparatio in the early days of sulphonamides.

French workers have lately suggested[1] that th leukæmic cell, which should be regarded not as a immature white blood cell but as an *abnormal* elemen creates a state of agranulocytosis by crowding out t normal granulocytes; they postulate an agranulocyt syndrome embracing both acute leukæmia and agranul cytosis proper.

I have often wondered whether some of the fulminatin agranulocytic complications in children, ascribed t sulphonamides, are not in reality rare instances of acut lymphatic leukæmia in the aleukæmic stage. The chil is usually very ill, with pyrexia and sore throat, an sulphonamides are given before the diagnosis is made Subsequent routine blood-counts may be indistinguish able from those in agranulocytosis. If the condition with no appreciable enlargement of lymphatic glands, i

achieve the fullest coöperation between himself and his fellow officers, particularly those in other departments. Conditions vary widely from Service to Service, and it would seem fruitless for a medical officer to have to accustom himself to three types of Service conditions.

These remarks apply more to the general-duty medical officer than to the specialist, and the case for a combined Services medical organisation deserves full consideration. I would like to see a combined *hospital* system, staffed by officers who have been recommended for specialisation from all three Services, the general-duty officer continuing to serve in only one of the Services.

J. C. E. PESHALL.

LEFT TURN

SIR,—As one who belongs to no political party—a plague on all their houses—I find the robust, if somewhat démodé, communism of Dr. Kirman rather refreshing.

I wonder how many of my generation, the fifth decaders, have ever thought of themselves as protégés of n ex-ruling class now desperately trying to ally themelves with a decaying bourgeoisie? It is true that octors are in one sense (and only one sense) a privileged lass, their quite special and unique privilege being to erve the sick of all classes; but I should not have hought many of them conscious of any particular 'dignity' unless it be the proper pride of decent men nd women trying to do a difficult job decently.

Slogans are at best only poor half-truths, but I submit hat, on balance, there is more to be said for "government of the doctors, by doctors and potential patients, for patients" than for "government of patients and doctors, by politicians, for politicians."

Crediton. L. N. JACKSON.

PSYCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—Letters criticising Dr. Milligan's article of Oct. 12 show considerable ignorance of the nature and effects of electric convulsive therapy. As I have had occasion recently to make repeated visits to St. James's Hospital, I can testify to the good results of the concentrated method for chronic types of neurosis.

Patients do not suffer mental anguish when having electric convulsive therapy, nor does its effectiveness depend, as has been naïvely stated, on giving a "shock" at the conscious level, and, as it were, frightening the patient out of his illness. It has nothing in common with the "shocks" given in the last century—e.g., at Bethlem when a patient was allowed to fall through a trapdoor into a cold bath. On this principle leptazol would be more effective, since with it the patient may remember horrifying sensations preceding the convulsion. In electric convulsive therapy this never happens and yet it is equally successful. Furthermore, if a patient is always anæsthetised before electric convulsive therapy it is just as efficient. I recently saw a striking recovery from long-standing agitated melancholia where the patient was unaware that she had had electric convulsive therapy, because 'Pentothal' had preceded each shock. The fact that outpatients almost never refuse to go on with electric convulsive therapy shows how little they mind it.

There is no a-priori reason why electric convulsive therapy should be reserved for the psychoses. Only experience can show if the treatment will benefit the chronic neurotic who has failed to respond to psychotherapy and who is tortured by anxiety or by *folie de doute* or endless ritualistic acts. If left alone he is more likely to die by his own hand or by intercurrent disease caused by inanition.

The objection that the patient's brain may be injured is surely one for the neuropathologist rather than the psychotherapist, yet Frostig and others in the U.S.A. have conducted animal experiments over a number of years without finding any irreversible changes with such electric currents. While it is possible that 20 or more treatments with electric convulsive therapy may in cases of idiosyncrasy cause localised organic changes, there is as yet no evidence of permanent impairment from Dr. Milligan's treatment. Since his ex-patients remain under repeated observation any such effects would soon become apparent to himself or the patient's relatives.

Dr. Milligan has certainly made out a prima-facie case for this type of treatment in chronic and intractable neuroses. Until further results are available it would surely be advisable for those who have had no experience of the treatment to refrain from highly emotional and even libellous attacks on a responsible and energetic group of psychiatrists.

London, W.1. A. SPENCER PATERSON.

HYPERTENSION AND CALCIUM INTAKE

SIR,—Your review last week of *Studies in Hypertony and Prevention of Disease* attributes to me statements which I never made, and suppresses essential facts which our investigation established. I never stated that the chief villain of hypertony is calcium, nor have I ever claimed that it has been established that calcium is an important factor in the ætiology of hypertony. Only one conclusion is made in regard to this substance: "Calcium administered *per os* has a blood pressure raising action." But it does not follow from this that it is a causal factor in hypertony. The minimum amount of the substance required to raise pressure has never been studied by me.

Out of 114 pages of our book only 14 were devoted to our calcium experiments. We have done a fair amount of work on cholesterol which I hope has advanced our knowledge of the substance considerably. But this is not commented on. The section "influence of high intakes," which contains by far the most important contribution in the book and establishes a principle which physicians and nutritionists will have to heed—a principle which invalidates a good many requirement values and makes nonsense of the phytic acid theory—is not even mentioned in your review. Nor is the very existence of the section under the heading "periodical examinations" brought to the notice of your readers—although this contains in many ways a report on a novel experiment of particular importance at the moment.

Why did you give a distorted description of the book? Evidently your concern was the attitude I have adopted towards the adulteration of our bread, which has offended certain persons in authority.

Even more amazing is the article on page 793 by Kesson and McCutcheon on Hypertension and Calcium Intake which begins: "The statement has been made that a high-calcium diet is an important factor in the production of hypertension in subjects over middle age." Would the authors please give the passages in my book in which I made such a statement?

Why should they have expected to find a low blood-pressure in osteoporosis, seeing that this condition is not a simple calcium deficiency? They naïvely admit that it is possible to have "calcification of arm and leg vessels" with rarefaction of the bones. It follows from this that we may have arteriosclerosis and even high blood-pressure in osteoporosis. These cases have no bearing at all on our problem. But there are some data which are relevant to it. There is a statement that the affluent classes, whose intake of calcium is unusually high, show a prevalence of arteriosclerosis and allied conditions.[1]

Strange are the experiments of Kesson and McCutcheon in regard to a high calcium intake. Considering that their paper is concerned with hypertony, it is remarkable that no records of blood-pressure readings are given, and no evidence is produced that the myocardium of these patients is in a sufficiently healthy condition to react to pressure-raising substances; nor are we told the type of controls used. The investigators evidently relied on X-ray findings to demonstrate their thesis. I hope they know that we may have arteriosclerosis without hypertony, and vice versa, and that hypertony cannot be diagnosed by X-ray examination. But X-ray does not even lend itself to demonstrate a moderate increase of arteriosclerosis, the method not being exact enough for such a purpose. In rabbits we have demonstrated, by analysing the tissue of the aortas, that a high calcium intake increases enormously the calcium content of these vessels.[2] Heubner[3] kept cats on a high calcium intake

1. Arteriosclerosis, ed. by E. V. Cowdry, London, 1933.
2. Harris, L., Ireland, J. T., James, G. V. *Brit. med. J.* 1941, i, 49.
3. Heubner, W. *Biochem. Zschr.* 1925, 156, 171.

Good progress was maintained, and at the end of four to five weeks the renal condition was normal except for a slight amount of albuminuria. Slight bowing at the fracture site had occurred and was corrected on a Thomas splint. The patient was evacuated to the U.K. seven weeks after the original operation.

The points of interest in this case seem to me to be: first, the cause of the rapid hæmolysis, which I conclude to be lysis in the blood (fourteen days old); secondly, the absence of any reaction at the time of the *transfusion, due to general anæsthesia; thirdly*, the absence of œdema, due to balanced fluid control and not endeavouring to flog a tired and very sick kidney; fourthly, the very high blood-urea level reached with recovery not beginning until four or five days after the decapsulation; and fifthly, the production of these changes by the decapsulation of one kidney alone.

Childwall, Liverpool. WILLIAM PARKE.

SIR,—While Mr. Reid and his colleagues (Nov. 23, p. 749) are to be congratulated on the recovery of their patient suffering from anuria, it should surely be emphasised that these patients not infrequently overcome their suppression of urine without all the special procedures suggested. We have recently had a patient at this hospital who had a transfusion reaction due to Rh incompatibility and suffered from severe oliguria, passing only 47 oz. of urine in ten days, compared to an intake of 18 pints by mouth and 11 pints intravenously during the same period. This patient went downhill, becoming more and more drowsy and œdematous, until she was comatose with a blood-urea of 320 mg. per 100 c.cm. Apart from alkalis, sedatives, and fluids (despite increasing œdema) she received no special treatment. Renal decapsulation was considered, but not favoured by the consulting urologist. On the 12th day sudden diuresis most dramatically set in, and the patient subsequently made a complete recovery.

It is agreed that the aim of all treatment must be diuresis, and once the kidneys begin to function again the patient will in all probability recover, even when this happens at a very late stage. One cannot help feeling that renal decapsulation and peritoneal dialysis are serious operations in a patient already dangerously ill and surely must, in such a case, carry a mortality of their own. Are they really justifiable while the causation of this condition remains obscure and patients can recover without surgical interference even if almost moribund?

St. Mary Islington Hospital, London, N.19. R. W. DANZIGER.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—With reference to Mr. Hermon Taylor's article of Sept. 28, the following case I saw in 1933 is of interest.

A woman, aged 48, had a gastric ulcer of the lesser curvature, as shown in a recent radiogram, which had been treated medically. At 8.30 P.M. on May 20, while standing behind the counter in her grocery shop, she was seized with generalised abdominal pain and collapsed. Her last meal had been at 4 P.M., when she had had bread and butter, fish, and a cup of tea. I saw her at 10 P.M. Her pulse-rate was 140 per min., temperature subnormal, and respirations 40 per min. Her abdomen was board-like and she was continually retching but was too weak to vomit. I diagnosed an acute perforation, but the patient and her husband were strenuously opposed to operation, and against my conscience I continued to treat her, pointing out the hopelessness of the prognosis without surgical treatment.

She was put in Fowler's position, given nothing by mouth, and kept on morphine until the fourth day, when to my surprise her distress disappeared. She was now taking sips of water.

On the seventh day she complained of pain in the 5th, 6th, and 7th left intercostal spaces, radiating to the left loin on the 10th day, and she became feverish. It was thought that she had a subdiaphragmatic inflammatory condition and she was admitted to the Midland Hospital, Birmingham. There was a patch of absolute dullness at the base of the left lung and the chest was explored, but only a little bloodstained fluid was obtained which showed no organisms on culture.

Her temperature gradually subsided and she made an uninterrupted recovery.

Hurst and Stewart[1] mentioned that they had seen three patients with typical signs of perforated gastric or duodenal ulcer recover with starvation and morphine, operation having been refused. In two, recovery was uneventful; the other only recovered after a series of operations performed, during the following 6 weeks, for perigastric and subdiaphragmatic abscesses and empyema. "It is remarkable," was the authors' comment, "that recovery should have taken place in the only three cases we have met in which rational treatment was refused."

Birmingham. S. SILVERMAN.

ICTERUS GRAVIS NEONATORUM

SIR,—I feel that Dr. Third's article (*Lancet*, Nov. 2, p. 635) should not be allowed to pass without comment. His cases were diagnosed during 1944 and 1945. Since that time a large series of publications have appeared, many dealing with the serological complexities of the disease, and I feel that the additional knowledge th provide justifies a rather less pessimistic view than th apparently held by Dr. Third.

Dr. Third has based his observations, as no doubt will readily agree, upon a very small series of cases, a it is not stated in his protocols for how long after bi the condition was allowed to continue untreated. was certainly unfortunate in finding two possi imbeciles in his small series, and if more cases had be covered the percentage of mentally affected might ha been considerably less. On the other hand it is unprov that the mental changes are the direct result of t yellow staining of the cerebral nuclei; and we are the opinion that the cerebral degeneration responsi for subsequent imbecility is the result of prolong cerebral anæmia. It is for this reason that I raise t question of the relationship of the duration of the disea post partum and the date when treatment was fir started.

I am in complete agreement with Dr. Third th further investigation is needed to elucidate the proble *There is little doubt that isoimmunisation of the moth* may eventually produce different pathological picture but *seldom is a case so clear-cut as to present,* Dr. Third suggests, a picture of jaundice without hæmo lysis. In fact I know of no reliable evidence to suppor the idea that jaundice in cases of this type is ever trul "toxic", and not solely due to hæmolysis. Dr. Thir considers that only the "erythroblastæmic" cases a worthy of transfusion: in our experience the case wit a typical blood picture is usually one where the diseas has reached its "agonal" stage, and even then trans fusion has proved of value. On the other hand, it desirable that infants should never reach that stage affection, and whereas we agree that Race's suggestio of injecting the specific polysaccharide hapten (if suc it proves to be) *to neutralise free circulating* antibod is the obvious theoretical desideratum, the early dete tion of the possibility of erythroblastosis by antenat serological testing affords an immediately available an practical alternative.

Jessop Hospital for Women, Sheffield. C. CHRISTOPHER BOWLEY.

THREE IN ONE?

SIR,—I was most interested in your annotation o Oct. 12, and would like to comment on one point. Yo suggest that if medical officers worked *in turn* in all thre Services there might be a wider variety of clinica experience than is obtained at present. This is true but it would endanger a very important part of th *medical officer's usefulness.*

Practice in the Forces is not merely a matter o prescribing the correct treatment; it is *necessary* t know the conditions under which the patient is living and the spirit of the Service, so *as to* understand the mental atmosphere, for instance, on the mess decks in a ship. What is required of a man in the performance of his duty must also be known. *The patient* has much more confidence in the medical officer who understands these things. *Regulations* can be learnt from the books, but it is by experience that things are *done* the best way. Experience alone can teach the medical officer how to

Parliament

QUESTION TIME

Parcels for Europe

In answer to a question, Mr. John Strachey announced that the Government had decided to allow individuals in this country to send food parcels to individuals in any country overseas including Germany. He was arranging for "Save Europe Now" to provide facilities for people who had not friends abroad but who wished to help. Parcels would be restricted to one a month with a gross weight of 7 lb., and only rationed foods, including goods on points, would be allowed. He was happy that it had now proved possible to make these arrangements because it was no longer possible for this country to send bulk supplies of food abroad. The considerable supplies sent last year represented a serious sacrifice. Today our stocks of food, particularly grain, were much lower than at this time last year and it was out of the question for us to make any diversions from them.

Food Ration in British Zone

Mr. R. R. Stokes asked the Minister of what the 1550-calorie ration in the British zone was comprised.—Mr. J. Hynd replied: The composition of the ration varies with the supplies available, and all the items on the ration do not, of course, figure in each day's diet. The following are the details:

Foodstuff	*Weight in ounces*	*Calorific value*
Bread	12½	875
Potatoes	12½	232
Other vegetables ..	2½	11
Skimmed milk ..	4·4	43
Cereal foods	1·9	176
Meat	0·6	28
Fish	0·75	29
Fats	0·25	51
Sugar	0·9	107
Cheese	0·08	5

World Cereals

Replying to a further question, Mr. Strachey said that the total exportable surplus of wheat and coarse grains for 1946–47 was estimated by the International Emergency Food Council at about 25 million tons. Total import requirements of wheat and coarse grains as presented to the council were about 35 million tons. This serious gap between supply and demand would no doubt be somewhat reduced by a careful scrutiny of the requirements submitted by various countries. In fact, however, the general world position was not our main immediate concern. Recent events in North America had gravely affected the ability of both the Canadian and the United States authorities to move wheat for export. The transport position in the United States would govern the flow of cereal supplies to this country over this winter rather than the amount of cereals potentially available in North America. These transport difficulties had already become sufficiently serious to deplete our stocks to a level much below that of this time last year. "It is for these reasons that I must warn the House that there is at present no possibility either of derationing bread or of diverting supplies to Germany or anywhere else. On the contrary, we shall have to take the most vigorous measures to keep our own stocks up to the minimum level at which we can be sure of meeting the present ration."

Employment of ex-Service Doctors

Mr. S. Hastings asked the Minister of Health how many ex-Service doctors were unable to obtain employment in general practice; and if he would make a statement as to the provision of employment for such doctors until the National Health Service Act came into operation.—Mr. Bevan replied: I regret I have not the information requested in the first part of the question. Ex-Service general practitioners can take the hospital posts and refresher courses available under the Government's postgraduate scheme and it is then open to them to buy or open a practice or to seek assistantships or other appropriate employment in the usual way during the interim.—Mr. Hastings: Is the Minister aware of the great difficulty there is among doctors in obtaining assistantships at the present time?—Mr. Bevan: Yes, I am aware that there is a difficulty. It is a difficulty which always arises immediately before great changes are made. We are doing our best to mitigate the hardships where we can.

Willesden General Hospital

Mr. E. H. Hardy asked the Minister whether he was aware that the committee of the Willesden General Hospital, a voluntary hospital, had refused to set up a consultative committee in defiance of his advice to all hospital authorities; and what further steps he proposed to take.—Mr. Bevan replied: I am drawing the attention of the hospital authority to the recommendation I have already made that there should be a nurses' representative council in every hospital.

Scottish Bill

In the House of Commons on Nov. 26, Mr. J. Westwood, the Secretary of State for Scotland, introduced the National Health Service (Scotland) Bill which was formally read a first time.

Medicine and the Law

Non-consummation and Nullity of Marriage

In J. *v.* J., reported in the *Times* of Nov. 23, Mr. Justice Jones refused a wife's petition for the annulment of her marriage where the husband, before the date of the marriage, had undergone an operation which rendered him sterile. Her counsel's arguments echoed phrases heard in the case of Cowen *v.* Cowen last year (*Lancet*, 1945, ii, 183, 215). One of the principal ends of marriage had been frustrated by the husband's operation. Mr. Justice Jones, however, finding that the wife was aware of the disability at the time when she agreed to marry, declined to annul the marriage. The surgeon, it seems, had refused to operate unless both parties signed a statement that they consented to, and appreciated the effect of, the operation. They both signed. The wife's evidence was that she hoped the operation would be postponed till after marriage; but the court found that she married with knowledge that it had been performed.

Her petition alleged inability to consummate or, alternatively, wilful refusal to do so. Before the Matrimonial Causes Act of 1937, sometimes called the "Herbert" Act, inability to consummate was the only ground on which a marriage, though not void, could be avoided. Section 7 of the Herbert Act made a marriage voidable on the additional ground of non-consummation due to the respondent's wilful refusal. Mr. Justice Jones held in the recent case that there was wilful refusal, though, as already stated, he held that the wife's prior knowledge of the husband's condition was fatal to her petition.

Consummation is construed as ordinary and complete sexual intercourse. In the Cowen case it was established that there is no consummation if the sexual act is so performed that its natural termination (the passage of the male semen into the woman's body) is artificially and intentionally prevented. Even in the circumstances of the Cowen case, however, the court was careful to add the warning that, if this incomplete intercourse took place with the wife's consent, and if she did not object till a later date, her petition for annulment would be rejected unless she could show some justification for the consent she had previously given. The basis of the recent decision in J. *v.* J. is the general principle, however, stated from time to time in litigation of all kinds, that a party cannot "approbate and reprobate." The House of Lords speeches in G. *v.* M. in 1885 contain dicta which are important. "Any act," said Lord Chancellor Selborne, "from which the inference ought to be drawn that during the antecedent time the party has, with a knowledge of the facts and of the law, approbated the marriage which he or she afterwards tries to get rid of, has taken advantages and derived benefits from the matrimonial relation which it would be unfair and inequitable to permit him or her, after having received them, to treat as if no such relation had ever existed. That explanation can be referred to known principles of equitable and, I may say, of general jurisprudence." The facts of the 1885 decision established no case whatever of the wife's pre-matrimonial assent. The husband in that case was found by the courts to have been impotent; that was not a matter of which the wife could have been aware before marriage. But the observations of Lord Selborne, cited above, were such as Mr. Justice Jones could not ignore.

and found that the arteries and tendons contain more calcium than other tissues on it. Judging by the data from animal experiments—and there would not be much left of physiology or pharmacology if such data were not valid for man—the 19 patients under a high calcium intake must have had increased deposits of calcium in the vessels as a result of the treatment; nay, more, a simple calculation shows that a pronounced positive calcium balance, extending over 15 months, and even over 18 weeks, must have caused an enormous accumulation of calcium in these patients, part of which without the slightest doubt must have been deposited in the vessels. The calcium obviously is somewhere in the organism; and this proves that no reliance whatever can be placed on X-ray in an investigation of this kind.

But let us disregard this vital fact for a moment. At any rate one case out of the 19 has shown an increase of arteriosclerosis demonstrated by X-ray whilst under treatment. Kesson and McCutcheon say that this was not due to the high calcium intake. But have they produced valid evidence that this is so? They have not, and they cannot produce such evidence. It is clear that they must admit, to put it at its lowest, that there is a *possibility* that in one case arteriosclerosis increased as a result of the treatment! They naïvely say that they supplemented the ordinary diet with calcium. Clearly a calcium intake which causes a positive balance for 15 months is not given in the interest of the patient. At the beginning of the experiment they could not know the results of this high calcium administration, and according to their own showing there is a *possibility* that they have actually inflicted an injury on at least one of the patients.

By adding calcium to bread the authorities concerned are conducting a larger experiment—on forty million human beings! Everybody admits that millions and millions of people do not need the added chalk. The possibility of their suffering injury by it cannot be excluded. These millions are exposed to an unnecessary risk. As a matter of fact it is certain that an intake of such a potent substance as calcium in unnecessary quantities must inflict injury. If it is retained it is bound to do harm, while if an unnecessary amount of calcium passes out via the kidney it causes unnecessary renal strain.[4] There is not a shadow of doubt that the additional chalk must in many instances cause injury and shorten life.

The attack on my calcium experiments can have only one object—to confuse the issue and to mislead. Let me quote what I really say: "In considering it [the adulteration of our bread] the matter in this volume can be disregarded entirely" (p. 10). I have always maintained that the onus of proving their case rests with the authority which forced the added calcium on us. They must produce solid reasons why the adulteration of our bread has become necessary, and they must prove that it cannot possibly do harm. It will be seen from my letter in your issue of Oct. 12 that those responsible for the added calcium have virtually admitted that when the recommendation was made there was no valid reason for it. On p. 9 of my book I say: "No physician outside bedlam would suggest that a high blood-pressure case should consume extra doses of blood-pressure raising substances." And this is exactly what is being inflicted on many people today.

I have suffered calumny and persecution because of my expression of these views. I was prevented from obtaining a research-worker during the war, and it has been quite impossible for me to get a paper published on calcium in relation to hypertony, apart from the intrinsic merit of my effort, simply because no editor dared to offend a highly placed personage! This book was published almost a year ago, yet only one medical journal has dared to review it up till now. And it is quite clear that the only type of review you dare to publish is the one you have actually published; and you have atoned for it by the prompt publication of that precious article with which I deal in this letter.

Well, my book is available, and your readers may judge. My experience is not a happy augury for the shape of things to come, when we shall have fully fledged Government scientists.

I. HARRIS.

Liverpool.

RESISTANT GONOCOCCI

SIR,—In the autumn of 1943 I had the care of a nur of gonorrhœa cases at Mombasa. At that time sul pyridine was the only remedy available. It soon bec apparent that a high proportion of infections contra in South African ports were resistant to sulpha dru so much so that the arrival of a ship from the south the inevitable prelude to a further batch of cases to treated by traditional methods. In most of thes definite unstained areola could be seen around isolated stained gonococcus, and this was assumed indicate the presence of a capsule. When this areola demonstrated in the first urethral smears taken admission it was possible to predict with confidence t chemotherapy would fail. The gonococci involved w thought to be specifically resistant to sulphapyridine this was the only drug generally accessible for s treatment in South Africa.

I write to you now because the same phenomenon appearing in a small group of penicillin-resist gonorrhœa cases under my care: it may indicate so link between the capsulated gonococcus and resista to a specific drug, though not necessarily to all forms chemotherapy at the same time (the first two penicill fast cases later yielded to sulphathiazole). Certain strai of capsulated gonococci have been described academicall and the coincidence of capsule and resistance in the cases may be merely accidental. All the same t relation might be worth investigating with bett facilities.

S.S. *Arundel Castle.* W. S. PARKER, Surgeon

A MORAL PROBLEM

SIR,—Your annotation last week raised seve interesting points. Personally I hope that a serio effort will be made to collect together the results of the experiments carried out on prisoners in Germ camps, and that anything of value will be publishe The reasons given against such publication seem to to be simply pernicious sentimentality. If I myself h been a victim, and some results of value or of interest h been obtained from my death, I am sure that I shou have preferred to know that this knowledge would ha been used and that I had not died entirely for nothin

At times I have felt a good deal of sympathy for son of those who were responsible for carrying out t experiments. Accounts of the trials leave little dou that many of the so-called scientists were men of academic standing, with no idea how to carry out experiment, and some were no more than irresponsib sadists; all these deserve the appropriate treatment the hands of the courts. But others were serious researc workers. If one were given the chance of using prisone for experiments which one believed to be of gre importance and value to mankind, what would one d particularly if government propaganda had convince one that the victims were dangerous criminals who we anyhow condemned to death, and likely to die in son particularly abominable manner? This is indeed moral issue, and I am not at all sure what I should myse have done. I have always been most fortunate, in th I have been able to obtain willing and coöperativ volunteers when I have wished to carry out experiments o man, but there are many types of investigation for whic one must hesitate to use such subjects. I believe tha while capital punishment is retained, condemne murderers should be given the opportunity of volunteerin to serve as subjects for experiments. The question rather different when the victims are innocent prisoner though to a keen research-worker with little contact wit the world outside his laboratory and who believes wha his government tells him the answer may be simpler.

The method in which these results should be publishe requires careful consideration. At all costs sensationalism must be avoided, and it might perhaps be as well to grad them as "confidential" and make them available onl to bona-fide investigators. Otherwise the press shoul be taken into the confidence of those responsible for th editing of the reports before publication; the averag journalist is a responsible person, and in this way accurat and unobjectionable reporting would be ensured.

KENNETH MELLANBY.

Department of Entomology, London School of Hygiene and Tropical Medicine.

APOTHECARIES' HONOURS

THE Society of Apothecaries of London have presented their medals in therapeutics to Sir Alexander Fleming and Sir Howard Florey in recognition of their work on penicillin. At the presentation ceremony on Nov. 28 Prof. E. C. Dodds likened the occasion to the gathering in 1892 at the Sorbonne, in Paris, when Lister delivered the main address at the celebration of Pasteur's seventieth birthday. As Lister said of Pasteur so might it be said of Fleming and Florey: "You have lifted the veil of mystery which throughout the centuries has covered the infectious diseases." These two men had added the final touch to Pasteur's brilliant series of experiments. No two men in history could claim to have saved more lives; and it was an added satisfaction that their discoveries could not be applied to destruction.

In reply, Sir Alexander Fleming recalled how the surgeons' complacency about sepsis had received a severe jolt in 1914. They had started to pour all kinds of chemicals into wounds to kill the microbes, but they had done more harm than good until they returned to their job of cleaning up the wounds. He compared the distressing scenes in a hospital for fractures in Wimereux in 1918 with the relative comfort of fracture cases in this war. Sir Howard Florey remarked on the astonishing series of chances which had led to the introduction of penicillin therapy. There were, he said, some hundred thousands of moulds closely allied to *Penicillium notatum*, and almost all were deadly poisons; yet *P. notatum* was the first to be investigated as an antibiotic. If they had begun with the poisonous species they might well have tired before they reached the one which proved to be non-toxic.

The society also debated the admission of women to its freedom. Mr. T. B. Layton urged the society to make itself a suitable body to play a responsible part in the National Health Service. The Government would not recognise such a body unless it contained women. The question will be decided by the Court of Assistants on Dec. 17.

Finally the Master presented a cheque and scroll to the retiring bedell, Mr. W. T. Withers, in recognition of 59 years of faithful and kindly service.

THE SISTER KENNY FILM

IN a film simply entitled *Sister Kenny*, the RKO Picture Corporation and Miss Rosalind Russell present a restrained biography of this provocative personality, based on Miss Kenny's book, "And They Shall Walk." Her early years as a bush nurse in Queensland introduce her to the disease which she makes her life study; left on her own without medical advice she treats the acute stage of infantile paralysis with hot packs, and then when she believes her patient to be cured she is faced with paralysis. This she treats by careful muscle re-education. Six cases under her sole care do well, and then, the epidemic having subsided, she reports to her nearest medical centre. The local doctor is astounded by her story, which she repeats at his request to the nearby orthopædic specialist; he is frankly incredulous and mildly insulting, even when she shows him one of her patients. Considerably nettled by this opposition to what appears to this young nurse as self-evident facts she boldly opens a small centre for treating by her methods the failures of more orthodox treatment. This centre is forced to close by local medical opposition, and then she enlists for World War I. She has decided to marry on her return, but a fresh polio epidemic in her home area claims her attention and then she goes, against the advice of her local doctor, to a larger outbreak in Brisbane. Here she meets the full force of orthodox medical opposition, and indulges in a public argument with the eminent orthopædic consultant. Some years later sees her undecided whether to go to Britain at the invitation of the L.C.C. or to stay at home to give evidence before a Royal Commission on her work; she goes to Britain, but is shortly recalled by public acclaim to a fresh epidemic in Australia. After her return the wholly unfavourable Royal Commission report is published, and a little later her book receives a storm of criticism. Disappointed yet undaunted the now elderly lady goes to U.S.A. on a long lecture tour, but is apathetically received. She decides to return home, but at the last moment is asked by the citizens of Minneapolis to open a treatment centre. Here her lifelong ambitions of treating acute cases early and of describing her methods to medical men are realised in spite of severe criticism of her work by a U.S. commission.

Although it comes from Hollywood, that centre of ballyhoo, and is concerned with a notably controversial subject, the film tells without undue sensationalism a sincere story of devotion to a cause. The medical profession is nobly represented, whether as the frankly admiring Dr. Alexander or the outraged Sir Charles Brack; but there is no hint that a knowledge of muscle exercises has leaked through to the doctors, who are shown treating their cases only with splints and black despair. Few will deny that doctors are, in the main, conservative, and that they have a deep and often soundly rooted objection to novel ideas on treatment devised by unqualified persons. But in this case, Sister Kenny's idea has been thoroughly examined and as thoroughly rejected by the main body of opinion here and in the U.S.A. Inevitably the film must leave in some lay minds the idea that a wonder treatment awaits but for the doctors' perversity. Is this quite fair to the public? It might be better if RKO had chosen a subject that doctors should have examined but have not. Perhaps they will try again. There should be no lack of suggestions.

ALL DONE BY SEALS

THE Christmas seals of the National Association for the Prevention of Tuberculosis are now well known. This year the design shows an old-fashioned lamplighter, with his ladder set against the lamp, under a starry sky.

It is impressive to realise how much work for the tuberculous depends on the sale of these coloured stamps. The association has worked for 45 years, by means of education, research, and propaganda, to reduce the disease. During the past year Dr. Santon Gilmour's report on tuberculosis in the West Indies has been published; the N.A.P.T. handbook of tuberculosis schemes has been revised and reissued; a new publication—*Tuberculosis Index and Abstracts of Current Literature*—has been started in association with the Tuberculosis Education Institute; and a new popular quarterly called *Health Horizon* has been founded. The association has continued to advise and educate the public by answering inquiries, by publishing non-technical leaflets and magazines (including one for young people called *The Lamplighter*, launched last June), and by its social welfare department. Refresher courses, conferences, and meetings have also been arranged.

All these activities are financed by the sale of Christmas seals. Twenty-four million of these, the gift of the Canadian Tuberculosis Association, are now available, and are sold at the rate of 4s. for a sheet of a hundred by the N.A.P.T., Tavistock House North, London, W.C.1.

University of Oxford

The following degrees were conferred on Nov. 23:

D.M.—L. J. Bussell (in absence).

B.M., B.Ch.—Robert Ebsworth Snow, T. A. Madden.

University of London

Sir Ernest Graham-Little has resigned from the chairmanship of the external council of the university owing to heavy parliamentary work. Sir Ernest has been chairman of the council for nearly 25 years.

University of Manchester

Mr. A. M. Boyd has been appointed full-time professor of surgery and director of the department of surgery from Dec. 25.

Mr. Boyd was educated at Haileybury, and studied medicine at St. Bartholomew's Hospital, qualifying M.B. in 1929. In 1931 he became a F.R.C.S. At St. Bartholomew's Hospital, after holding several other posts, he was appointed demonstrator in anatomy, and for three years was an assistant in the surgical professorial unit. He was surgeon to an E.M.S. hospital in 1939 and 1940, before joining the R.A.M.C. Early in 1941 he was posted to the Middle East, and he served in Egypt and Palestine for four and a half years. In 1942 he was promoted to lieut.-colonel and placed in charge of the surgical division of 63 General Hospital, Cairo, where under his direction a centre for vascular injuries was established. He returned to England in November, 1945, and resumed his duties at St. Bartholomew's Hospital, where he became an assistant surgeon last April. His special interest has been peripheral vascular disease, on which he gave a Hunterian lecture in 1935; he has published a number of papers on this and other subjects.

University of Leeds

Dr. B. N. Tattersall has been appointed a full-time lecturer in medicine.

British Postgraduate Medical School

Dr. Denis Hill has been appointed consultant in medical psychology at the school in succession to Dr. Eliot Slater, who has resigned. The L.C.C. have given him permission to hold this new appointment simultaneously with his present post of electroencephalographer at the teaching and research laboratory at the Maudsley Hospital.

Courses for Medical Artists

Arrangements have been made for student medical artists to be accepted at the Central Middlesex Hospital for a three months' course at a fee of 15 guineas.

Diary of the Week

DEC. 8 TO 14

Monday, 9th

Medical Society of London, 11, Chandos Street, W.1

8.30 P.M. Dr. F. T. Evans, Dr. Cecil Gray: Modern Anæsthesia.

Tuesday, 10th

Royal College of Physicians of London, Pall Mall East, S.W.1

5 P.M. Sir Arthur MacNalty: History of State Medicine in England: From the Accession of Queen Victoria to the General Board of Health. (First FitzPatrick lecture.)

Royal Society of Medicine, 1, Wimpole Street, W.1

5.30 P.M. *Psychiatry.* Leucotomy as an Instrument of Research: Dr. A. Meyer, Dr. T. McLardy (Neuropathological Studies); Dr. S. Last, Dr. G. Greville (Electroencephalographic Studies).

Chelsea Clinical Society

6.30 P.M. (South Kensington Hotel, 41, Queen's Gate Terrace, S.W.7.) Dr. Stanley Leader, Mr. Robert Cutler: Plastics in Surgery and Medicine.

London School of Dermatology, 5, Lisle Street, W.C.2

5 P.M. Dr. R. M. B. MacKenna: Principles and Practice of Treatment.

Edinburgh Postgraduate Board for Medicine

5 P.M. (Royal Infirmary.) Prof. Guy Marrian, F.R.S.: Biochemist's Approach to Problems of Pharmacological Activity.

Wednesday, 11th

Royal Society of Medicine

4.30 P.M. *Physical Medicine.* Dr. E. L. Sturdee, Dr. Marjory Warren, Dr. A. R. Neligan: Contribution of Physical Medicine in the Care of the Chronic Sick.

Royal Institute of Public Health and Hygiene, 28, Portland Place, W.1

3.30 P.M. Sir Allen Daley: Public-health Services of London During the Past Hundred Years.

Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1

2.30 P.M. Prof. Harold Burrow: Future Control of Abattoirs and Knacker Yards.

Society of Chemical Industry

6.30 P.M. (Chemical Society, Burlington House, Piccadilly, W.1.) Mr. D. P. Hopkins: Fertilisers, Manures, and Nutrition.

Association of Industrial Medical Officers: Scottish Group

3 P.M. (Institute of Hygiene, University of Glasgow.) Prof. T. Ferguson and assistants: Symposium on Occupational Medicine.

Thursday, 12th

Royal College of Physicians

5 P.M. Sir Arthur MacNalty: History of State Medicine in England: Medical Department of the Privy Council. (Second FitzPatrick lecture.)

Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2

5 P.M. Mr. W. Rowley Bristow: Injuries of the Peripheral Nerves in Two World Wars. (Robert Jones lecture.)

Royal Society of Medicine

8 P.M. *Neurology.* Dr. L. Guttmann, Mr. E. W. Riches, Dr. D. Whitteridge, Dr. P. Jonason: Treatment and Prognosis of Traumatic Paraplegia.

Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, W.1

8 P.M. Prof. B. S. Platt: Colonial Nutrition and its Problems.

London Jewish Hospital Medical Society

8.30 P.M. (Woburn House, Upper Woburn Place, W.C.1.) Mr. S. I. Levy: Principles of Urinary Surgery. (Presidential address.)

Middlesex County Medical Society

4 P.M. (Redhill County Hospital, Edgware.) Clinical meeting.

Socialist Medical Association

7.30 P.M. (296, Vauxhall Bridge Road, S.W.1.) Dr. J. Tylor Fox: Social Aspects of Epilepsy.

London School of Dermatology

5 P.M. Dr. F. R. Bettley: Seborrhœic Dermatitis.

Friday, 13th

Royal College of Obstetricians and Gynæcologists, 58, Queen Anne Street, W.1

5 P.M. Mr. Victor Bonney: Myomectomy.

Royal Society of Medicine

3.15 P.M. (Manchester Royal Eye Hospital.) *Ophthalmology.* Prof. Geoffrey Jefferson: Surgery of Intracranial Aneurysms. Cases will be shown.

5 P.M. *Clinical.* Cases will be shown at 4 P.M.

8 P.M. *Radiology.* (Joint meeting with the British Institute of Radiology and the Faculty of Radiologists at 32, Welbeck Street, W.1.) Carcinoma of the Stomach: Dr. J. L. Grout (X-ray diagnosis); Mr. H. Rodgers (Gastroscopy).

Royal Sanitary Institute

10.30 A.M. (Sessional meeting, Warrington.) Dr. S. F. Allison: Welfare of Old People. Dr. J. E. Nicole: Mental Health of the Elderly.

Royal Institution, 21, Albemarle Street, W.1

9 P.M. Mr. C. R. Harington, PH.D., F.R.S.: Body's Chemical Mechanisms of Defence.

London Chest Hospital, Victoria Park, E.2

5 P.M. Dr. Franklin Wood: Recent Advances in the Radiology of the Lungs.

Saturday, 14th

Royal Society of Medicine

10 A.M. (32, Welbeck Street, W.1.) *Radiology.* (Joint meeting, continued.) Carcinoma of the Stomach: Prof. M. J. Stewart, Mr. Hermon Taylor, Dr. G. C. Fairchild, Mr. Alan Shorter, Dr. D. Jennings.

Notes and News

BIRTH-CONTROL

WITH opening speeches by a geneticist, a gynæcologi a general practitioner, and a judge of the high court, m aspects of birth-control were considered at last week's d cussion by the Royal Society of Medicine. Dr. E. B. Fo said that the question of voluntary control because of t risk of transmitting hereditary disease does not arise ve often, since most of the conditions themselves restrict proc ation. Mutation, he said, is a rare phenomenon, 1 in 150,0 being a high frequency in man; and the balance must struck between mutation and selection. The chances transmission depend on whether the condition is heter zygous or homozygous, and on the kinship of the parents.

Mr. **Aleck Bourne**, discussing the harm that may possib be done by the various forms of birth-control, said th chemical spermaticides probably do little damage, apart fro minor irritation of the vagina with preparations containi quinine, or lactic acid in strengths over 3%; there is n evidence of an increased incidence of vaginitis among wome who use this method. The occlusive pessary which along wit a spermaticide is the method of choice, is also harmles Intra-uterine foreign bodies, now increasingly fashionabl are liable to cause pressure ulceration and infection. Th Gräfenberg ring is unreliable, and acts, moreover, as a abortifacient after conception in the fallopian tubes; i is thus illegal. Douches are useless. Finally, coitus interruptu is both unreliable and bad, leaving the woman, who does no *attain an orgasm, with unresolved pelvic congestion*; if thi is repeated often enough, neurosis ensues. The sustained us of contraceptives deprives the woman of the intangibl physiological stimulus, quite apart from the joy of having family, which is derived from childbearing. It is debatabl whether continued contraception causes sterility, except wit a foreign body in the uterus, or with coitus interruptus whic may interfere with ovulation. There is no substantial evidenc that chemicals introduced into the vagina in spermaticide interfere with absorption of hormones from the semen; an there is no indication of deleterious effects from the intermittent use of contraceptives to space pregnancies. The epoch has changed inexorably and irreversibly since the Victorian era with its habit of yearly childbearing. Women now view childbearing differently: "those who would abolish contraception must abolish the circumstances which have brought it into being."

Dr. **Kenneth McFadyean** pleaded for premarital instruction by doctors, who should themselves receive mor instruction. A chemical contraceptive with an occlusiv pessary is, he said, infallible, harmless, and devoid o anatomical or æsthetic objections.

Sir **Travers Humphreys** said that the practice of contraception is not unlawful. Marriage is a contract, of which consummation is an implied condition; and non-consummation is in most countries a ground for annulment. Last July the Court of Appeal held that a marriage is consummated if penetration is followed by *emissio seminis*; thus a wife may seek annulment if a rubber sheath is used. The reverse does not hold true: if the wife excludes the chance of pregnancy by herself practising contraception there is no ground for divorce. Abortion is undoubtedly criminal; therapeutic necessity is the only ground on which abortion can be approved or excused, and "I sincerely hope that neither by Parliament nor by the judges will the decision by Mr. Justice McNaughton be doubted." The matter is not so much one of law as of the good sense of the jury. The test is, does the doctor honestly believe that it is essential in the interests of the woman's health to do the operation? Here the doctor is put in the same place as the surgeon; to cut off a leg is a serious assault, and the only reason it is not criminal is the interest of the patient's health and life. The patient's personal wish is no defence in law; any doctor, for example, performing an operation for sterilisation simply at the patient's wish is exposing himself to a charge of criminal assault.

TUBERCULOSIS ALLOWANCES

FOR dependent children the Minister of Health has authorised, with effect from Dec. 16, the following payments under the scale of tuberculosis allowances laid down in memorandum 266 T:

	s.	d.
aged 11 and under 16	10	6
aged 5 and under 11	9	0
aged under 5	7	6

MALNUTRITION
IN RELEASED PRISONERS-OF-WAR AND INTERNEES AT SINGAPORE

J. B. MITCHELL
M.B. Lond.
LATELY MEDICAL SPECIALIST
R.A.M.C.

J. A. BLACK
M.B. Camb., M.R.C.P.
GRADED PHYSICIAN
R.A.M.C.

THIS report deals with 1230 patients admitted to the 17th British General Hospital, Singapore, between Sept. 9 and Oct. 8, 1945, mainly from camps in Singapore, Sumatra, Java, Borneo, Sarawak, and Bangkok. Of these, 86% were British Servicemen and civilians, the rest being mainly Australian and Dutch; only 1·6% were women. The greater part were admitted because, in the opinion of the camp doctors, they were not fit to make a voyage in a fully equipped hospital ship.

Nearly all these patients had been in captivity since February or March, 1942. The degree of maltreatment imposed by the enemy varied in the different camps, but usually the diet was deficient in proteins, fats, and vitamins. Rice, the staple article of diet, was usually highly polished. Most camps saw a quantitative reduction in rations early in 1945, which was maintained.

Burgess and Cruickshank (1946) stated that the diet at the military camp at Singapore supplied about 2500 calories daily, though in the last year the figure fell to 2000 calories, and that it was unbalanced in respect of the components of the vitamin-B complex. Bennet (1946), describing conditions in Formosa, spoke of the importance of conditioning factors—the harsh standards of fitness for work enforced by the Japanese and the prevalence of diarrhœa.

One of our patients gave this account of his diet between August, 1944, and August, 1945, when he was doing heavy manual work in Sumatra: rice 320–400 g., tapioca meal 70–100 g., daily; vegetables variable, consisting of jungle roots and leaves; fruit, usually green mangoes, issued occasionally; meat, a cube about the size of a large lump of sugar, issued every fifth or sixth day; meat bones used to be boiled again for soup and finally ground up and eaten.

The diet in a prison holding British civilians in January and February, 1944, consisted of a pint of hot water at 8 A.M., and $^1/_2$ pint of cooked rice with about a dessertspoonful of curry sauce at 11.30 A.M. and again at 6 P.M. The rice was often rancid.

Rice-polishings and synthetic vitamin preparations were always scarce and often unobtainable.

ANALYSIS OF CASES

Nearly all the patients admitted to the hospital in the month under review were extremely wasted. Many men admitted for malaria or diarrhœa had or developed signs of vitamin deficiency. The patients were admitted for the following disorders:

Disorder	*Cases*	
Malnutrition	577	(*46·9%*)
Malaria	73	(*5·9%*)
Dysentery or diarrhœa	87	(*7·1%*)
Surgical complaint	82	(*6·7%*)
Some other disease	163	(*13·3%*)
Mild malnutrition (ambulant cases)	81	(*6·6%*)
Unclassifiable (inadequate case-notes)	167	(*13·6%*)
Total ..	1230	

In the 577 cases admitted for malnutrition the outstanding lesions were as follows:

Outstanding lesion	*Œdematous cases*	*Non-œdematous cases*	*Total*	
Amblyopia	8	28	36	(*6·2%*)
Riboflavin deficiency ..	0	3	3	(*0·5%*)
Skin lesions	9	16	25	(*4·3%*)
Tongue lesions ..	51	59	110	(*19·1%*)
Neurological	88	64	152	(*26·3%*)
Other lesions	197	54	251	(*43·5%*)
Totals ..	353	224	577	

GENERAL MALNUTRITION

Many combinations of signs due to food deficiency were seen. Symptoms and signs varied in severity from simple wasting, with or without œdema, as seen in ambulant cases, to extreme emaciation and inanition.

In the most severe cases there was a history of having been in bed for two months or more and of being unable to assimilate the increased diet on liberation. There was always a history of passing frequent watery stools for three weeks or more. On examination lethargy was present; it took an abnormally long time to make the patient fully awake. Laycock (1944), describing starvation in China, remarked on the tediousness of extracting a history, and we found the same thing. When the patient was fully roused, orientation in time and space was normal. Speech and movements were feeble and slow, the voice weary, and the expression lethargic and immobile. There was no complaint, no desire for food, and apparently no desire to live. Respirations were slow and shallow, pulse feeble, and blood-pressure subnormal. Emaciation was extreme. The skin was coarse, wrinkled, and dry. Especially over the backs of the hands, elbows, knees, ankles, and neck it was thickened and scaling. The mucosæ were pale, and the tongue small and sometimes reddened. The mouth was dry. Œdema varied from a little pitting over the dorsa of the feet to massive œdema with multiple effusions into the serous cavities. Œdema sometimes increased during recovery.

Signs of vitamin deficiency often appeared after an improvement in the diet, occasionally at an unexpectedly late date and after several weeks' hospital diet and vitamin therapy, and they often became more pronounced after a fever. An exception to this was the reduction in œdema which often took place during an attack of malaria or of diarrhœa.

CASE 1.—A male civilian, treated for several months for peripheral neuritis and amblyopia, had been on a good diet and vitamin therapy for two weeks before admission on Sept. 11. He complained of blurred vision and numbness and tingling in the feet. He was very wasted; tongue red and smooth; knee, ankle, and biceps jerks not elicited. The ophthalmologist reported a paracentral scotoma. The patient was given hospital diet, with 6 compound vitamin tablets daily and 10 mg. of thiamine intravenously daily. Nine days after admission he suddenly became weaker in the legs, with gross ataxia of both arms and legs. Three weeks later there was only slight improvement.

CASE 2.—A bombardier, who on admission was grossly œdematous, with ascites and bilateral pleural effusions, severe anæmia, red smooth sore tongue, tachycardia, diarrhœa, and pellagrous skin lesions on the backs of the hands and forearms. After an initial general improvement he developed an empyema five weeks later. Thereafter his condition rapidly deteriorated and a well-marked angular stomatitis appeared. His skin and tongue continued to improve in appearance up to the time of his death.

AMBLYOPIA

Ocular deficiency symptoms appeared as early as four months after captivity. The average time was about a year, but some cases did not develop for more than three years. They were often unassociated with other signs of vitamin deficiency.

Photophobia and a burning sensation in and tiredness of the eyes were early symptoms. Supra- and retro-orbital headache was also present. Defective vision usually came on later. Blurring of letters and missing letters and lines when reading print, and failure to recognise faces, were noticed. Of the cases examined, about 13% had a vision of 6/60 or less in each eye, and the remainder 6/18 or less. Visual acuity was about equal in the two eyes.

Corneal and conjunctival sensation was normal, and the corneal changes which have been described in association with riboflavin deficiency were not seen by the

Royal College of Surgeons of England

At a meeting of the council held on Nov. 29, with Sir Alfred Webb-Johnson, the president, in the chair, the following resolution was passed:

> "The Council desires the Negotiating Committee to enter into discussions and negotiations with the Minister on the Regulations authorised by the National Health Service Act."

Sir Cecil Wakeley was appointed Bradshaw lecturer for 1947. Dr. Frank H. Lahey, of Boston, was appointed to deliver the first Cecil Joll lecture in September, 1947.

It was decided to publish a periodical containing news items and college lectures.

The Association Française de Chirurgie has given 50,000 francs to the college's rebuilding fund.

The council, having acceded to requests from the Royal Australasian College of Surgeons, from the medical faculty of the Egyptian University, Cairo, and from the Director-General of Medical Services in India to conduct the primary F.R.C.S. examination overseas, has appointed the following examiners for this purpose: Sir Heneage Ogilvie, Prof. B. A. McSwiney, and Prof. G. Hadfield. They are due to leave London on Dec. 8, and the examinations will begin in Cairo on Dec. 12, in Madras on Dec. 23, and in Australasia on Jan. 6. The examiners should arrive back in this country about the end of January. Altogether 224 candidates will be examined—32 in Cairo, 65 in Madras, 63 in Melbourne, 29 in Sydney, and 35 in Dunedin.

Royal Society

The following have been elected officers of the society for the coming year:

President, Sir Robert Robinson; treasurer, Sir Thomas Merton; secretaries, Sir Alfred Egerton and Sir Edward Salisbury; foreign secretary, Prof. E. D. Adrian, M.D.; members of council, Dr. C. H. Andrewes, M.D., Prof. W. T. Astbury, Prof. W. Brown, Mr. E. C. Bullard, Prof. A. C. Chibnall, Prof. C. A. Lovatt Evans, M.D., Prof. N. Hamilton Fairley, M.D., Prof. R. A. Fisher, Prof. S. Goldstein, Prof. E. L. Hirst, Prof. H. W. Melville, Prof. M. H. A. Newman, Prof. M. L. E. Oliphant, Mr. C. F. A. Pantin, Prof. H. H. Read, Sir Reginald Stradling.

The two royal medals for the year have been awarded to Sir Lawrence Bragg, F.R.S., for his researches in the sciences of X-ray structure analysis and X-ray spectroscopy, and to Mr. C. D. Darlington, D.SC., F.R.S., for his researches in cytology and genetics. The Copley medal has been awarded to Prof. E. D. Adrian, O.M., for his researches on the fundamental nature of nervous activity, and recently on the localisation of certain nervous functions.

Royal Sanitary Institute

The Benjamin Ward Richardson lecture will be delivered at the institute on Dec. 11, at 2.30 P.M., by Prof. Harold Burrow, whose subject will be Future Control of Abattoirs and Knacker Yards. At a sessional meeting in Warrington, at 10.30 A.M. on Dec. 13, Dr. S. F. Allison will speak on the Welfare of Old People, and Dr. J. E. Nicole on the Mental Health of the Elderly.

L.C.C. Mental Service

The following medical superintendents have now been confirmed in the promotions which they received on a temporary basis during the war: Dr. A. C. Dalzell, Friern Hospital; Dr. J. F. MacMahon, the Manor; Dr. L. T. Hilliard, Fountain Hospital; Dr. J. H. Watkin, Leavesden Hospital; Dr. Louis Minski, Sutton Emergency Hospital; Dr. A. B. Stokes, Maudsley Hospital.

Dangers of Raw Meat

The Ministries of Food and Health have circulated a warning against eating pork, pork sausage meat, ham, or any other pork product unless it has been thoroughly cooked. They also call attention to the dangerous practice of spreading raw sausage meat on bread; it will be recalled that this substitute for meat paste has been a potent cause of trichiniasis.

Certificates for Air Travellers

Doctors who give vaccinations and inoculations to intending air passengers are asked to use the "International Certificate of Inoculation and Vaccination" (Form 3150) when recording them. The forms can be obtained by the passenger from the agency from which he receives his ticket and flight information. The use of any other form may lead to delays and quarantine in foreign countries where only the international certificate is officially recognised.

Appointments

BEAL, J. R., M.D. Manc., D.P.H.; senior T.O., Northumberland.
COLBECK, J. C., M.B. Lond.: director of pathological and laboratory services, West Riding of Yorkshire.
DAVIS, H. S., M.B. Camb., M.R.C.P.: physician to outpatients Hampstead General and North-West London Hospital.
PETERS, H. J., M.B., B.HY. Durh., D.P.H.: M.O.H., Stockton-on-Tees
SMITHARD, E. R. H., M.D. Lond., D.P.H.: M.O.H., Lewisham.

Ministry of Health*:

Senior Medical Officer:

LILICO, G., M.B. Edin., D.P.H., M.O.H., Derby, recently seconded to UNRRA.

Medical Officers:

- BOUCHER, C. A., D.M. Oxfd, D.P.H., formerly A.R.P.M.O., Shoreditch, at present temp. M.O. at Ministry.
- GORRIE, MARY G., M.D. Glasg., D.P.H., regional M.O. for maternity and child welfare. Aberdeen and Kincardine, late temp. M.O. at Ministry.
- HERBERT, ANNE E. M., M.R.C.S., D.P.H., M.O., Welsh Board of Health.
- HIRST, KATHERINE M., M.B. Lond., D.P.H., deputy M.O.H., Islington.
- MACGREGOR, I. M., M.B. Glasg., D.P.H., A.M.O.H., Bristol, late colonel R.A.M.C.
- MANSON, MARGARET M., M.B. Edin., D.P.H., temp. M.O. at the Ministry.
- MARTIN, A. E., M.D. Manc., D.P.H., senior A.M.O.H., Leicestershire
- MURRAY, L. H., M.D. Durh., D.P.H., superintendent, Lanchester Joint Hospital Board, co. Durham.
- ROSS, J. M., M.B. Aberd., A.M.O.H., Lancashire, seconded as temp. M.O. to the Ministry.
- TAYLOR, I., M.B. Lond., M.R.C.P., D.P.H., divisional M.O., L.C.C.
- WINNER, ALBERTINE L., M.D. Lond., M.R.C.P., consulting medical practice, lieut.-colonel R.A.M.C.

* Appointments subject to confirmation

Examining Factory Surgeons:

- FOSTER, A., M.B. Glasg.: Port Glasgow.
- GAUNTLETT, E. G., C.B.E., D.S.O., M.B. Lond., F.R.C.S.: Braintree.
- GREEN, J. W., L.R.C.P.I.: Waltham Abbey, Essex.
- HENDERSON, A. G., M.B. Edin.: Arbroath.
- JACKSON, F., M.B. Manc.: Kirkham.
- LIDDELL, C. M., M.B. Aberd.: Peterculter.
- SULLIVAN, D., M.B. N.U.I.: Bilston, Staffs.
- WILLIAMS, R. E., L.M.S.S.A.: Godalming.

London County Council Central Medical Staff Assistant Medical Officers:

- COPITHORNE, R. E. C., M.R.C.S., D.C.H.
- MCKENDRICK, E. M., M.B. Glasg.
- MCMICHAEL, J. K., M.D. Edin.
- SUMMERS, F., M.B. Lond.

Colonial Service:

- CARUANA, S., M.B., B.SC.: M.O., Sierra Leone.
- CHARLTON, D. W. F., M.R.C.S.: M.O., Kenya.
- DAVIES, R. G., M.B. Lond.: M.O., Kenya.
- DUFF, A. R., M.B. Edin.: M.O., Uganda.
- EDDEY, L. G., M.B. Aberd., D.T.M. & H.: D.D.M.S., British Guiana.
- FURNESS, J. E., M.B. Lond.: M.O., Nigeria.
- GLASS, G. M., M.B. Belf.: M.O., Sierra Leone.
- ISAAC, R. H., M.R.C.S.: M.O., Malaya.
- JOYNER, C. M., M.B.: district M.O., Bahamas.
- LANE, J. P., M.B. N.U.I., F.R.C.S.: M.O., Tanganyika.
- MCADAM, I. W. J., M.B. Edin., F.R.C.S.: M.O., Uganda.
- RAPER, A. B., B.SC., M.D. Leeds, M.R.C.P.: M.O., Uganda.
- SCOTT, D., M.B.: M.O., Gold Coast.
- SCOTT, EDITH, M.B. Aberd., D OBST.R.C.O.G.: M.O., Nigeria.
- SMARTT, C. G. F., M.R.C.S.: M.O., Tanganyika.
- STECHER, S., M.D. Vienna: M.O. (grade C), Trinidad.
- STRUDWICK, R. H., M.B. Birm.: M.O., Nigeria.

Births, Marriages, and Deaths

BIRTHS

BROOK.—On Nov. 27, the wife of Dr. Bevis Brock—a son.
BUTLER.—On Nov. 26, at Buckhurst Hill, Essex, the wife of Mr. E. C. B. Butler, F.R.C.S.—a son.
CONWAY.—On Nov. 20, the wife of Dr. D. J. Conway—a daughter.
GRAY.—On Nov. 22, the wife of Dr. George Gray—a son.
HANBURY.—On Nov. 24, in London, the wife of Dr. Paul Hanbury—a daughter.
MALLOWS.—On Nov. 26, at Weymouth, the wife of Surgeon Lieutenant H. Russell Mallows, R.N.V.R.—a daughter.
SCHRYVER.—On Dec. 1, at Epsom, Dr. Nancy Richardson, wife of Peter Schryver—a son.

MARRIAGES

BRADY—AMBROSE.—On Nov. 26, in London, Surgeon Lieutenant Thomas Joseph Brady, M.R.C.S., to Margaret Mary Ambrose.
LONG—VLASTO.—On Nov. 28, in London, Aidan Long, M.B., to Helen Vlasto.
ROSE—MIETH.—On Nov. 28, in London, Louis Rose, M.R.C.S., to Jolanda Ingrid Gertrud Mieth.
TRINGHAM—SHERWOOD.—On Oct. 26, at Hong-Kong, Surgeon Lieutenant Robert Tringham, M.B., R.N.V.R., to Junior Commander Ida Seaman Sherwood, A.T.S.

DEATHS

GAMGEE.—On Nov. 27, Katherine Mary Lovell Gamgee, M.R.C.S. D.P.H.
HAYTHORNTHWAITE.—On Nov. 24, at Little Hayes, King's Langley, Herts, Izset Mead Haythornthwaite, L.R.C.P.I., aged 87.
HERBERTSON.—On Nov. 23, at Ferring-by-Sea, John Richmond Herbertson, M.B. Glasg.
HONEYMAN.—On Nov. 24, William Murray Honeyman, B.SC., M.B. St. And., M.R.C.P., squadron-leader R.A.F.V.R., aged 35.
IRVINE.—On Nov. 21, at Lewes, Sussex, Maurice Lionel Corrie Irvine, M.D. Lond., D.T.M. & H., lieut.-colonel I.M.S.

On admission (Sept. 12) he was emaciated. The skin was rather dry. He looked exhausted and spent most of the day sleeping. He said he felt ill and weak, especially in the legs and hands. Doing up his pyjama buttons was difficult owing to clumsiness of the fingers. He had a smooth magenta tongue. Pellagrous skin was seen round the ankles and knees, and on the backs of the hands. Extensor hallucis and peroneal muscles were very feeble on both sides; less severely affected were the extensor digitorum, tibialis anticus, quadriceps femoris, forearm extensors, and the grip on both sides. There was disproportionate wasting of the legs, thighs, and forearms. The muscles were hypotonic.

There was a minimal response to all tendon reflexes tested. Abdominal reflexes were not elicited. Sensation of pinprick was generally diminished, increasing peripherally. Below about the middle of the legs and below the elbows discrimination between sharp and blunt was lost. Heat and cold sense was lost in a band about 3 in. wide around the ankles. Joint sense in great toes diminished. Tendo-Achillis sensation reduced. Other systems: no abnormality found. Urine and blood picture normal.

He was given the ordinary hospital diet, with 6 compound vitamin and 6 'Benerva' tablets, nicotinic acid 200 mg., ascorbic acid 50 mg., and 'Vegamite' 3 drachms daily. He took his food fairly well and gained a stone in a fortnight.

Twelve days after the first examination he looked cheerful and well, his face had filled out remarkably, and he had put on muscle, especially about the shoulder girdle. He complained of unsteady gait; numbness, tingling, and clumsiness of the hands; and flatulence after meals. Other changes noted on re-examination were: improvement in power, well marked in the forearms, less so in the thighs, and slight in the legs; tendon reflexes all brisk; ataxia less (could now walk, though with a very drunken gait); loss of joint sense less; loss of sensation to pinprick increased; skin and tongue normal.

There were 2 cases (1 and 4) where severe ataxia developed in hospital.

CASE 4.—A male civilian, aged 54, had been interned since February, 1942. Shortly after release he noticed some numbness in the legs and hands. For several months he had had difficulty in reading.

On admission to hospital he was given the ordinary diet, and received every day 6 compound vitamin tablets and 150 mg. of ascorbic acid by mouth, and 50 mg. of thiamine intramuscularly. Nine days after this treatment began he suddenly found that he was unable to walk or write.

On examination general muscular weakness was found, increasing peripherally. Tendon and abdominal reflexes were not elicited. Plantar response minimal and flexor. Sensation to pinprick generally reduced; appreciation of sharp and blunt lost below right knee. Loss of joint sense of thumbs, right wrist, and great toes. Gross ataxia of arms and legs. Some pallor of the disks on the temporal side. Cranial nerves otherwise normal. Mentality and memory normal.

These 2 cases have some features in common with those described by Spillane and Scott (1945). The development of gross ataxia while on large doses of thiamine is of interest; similar observations have recently been reported by Clarke and Sneddon (1946).

PETECHIAL RASHES

Petechial rashes were seen in the most severe and least severe cases, and in patients who had been in hospital several weeks. The rash came on suddenly. The common situations were the forearms, round the shoulders, over the tibiæ, and on the back just below the shoulders. In most cases pinching or stroking the skin produced ecchymoses and linear petechiæ. This test was positive only in the affected regions. Hess's test was negative.

These rashes were not necessarily associated with anæmia, and in those cases where examinations were carried out neither the spleen nor the lymphatic glands were enlarged, and there was no abnormality of the joints, interdental papillæ, white-cell counts, clotting-times, or bleeding-times. The condition did not respond to large doses of ascorbic acid or of nicotinic acid. It usually lasted 8–14 days, and in a few cases relapsed once.

CARDIOVASCULAR DISTURBANCES

Disturbances of the cardiovascular system could be divided, according to the response to parenteral thiamine, into those which responded rapidly, those which improved in about 5–10 days, and cases of unexplained tachycardia which did not respond. The first group consisted of 2 cases only and these were the only patients who showed engorgement of the veins of the neck.

CASE 5.—A lance-corporal, aged 29, had had occasional swelling of the feet for two years. Three weeks before admission his feet became more swollen, and he had breathlessness on exertion, loss of appetite, and slight cough.

On examination he was dyspnœic at rest, with some cyanosis. Gross œdema of legs and feet; much ascites; basal congestion; and engorgement of neck veins. Pulse-rate 144 per min. (regular); blood-pressure 160/120 mm. Hg; heart much enlarged; gallop rhythm. Intravenous thiamine and digoxin begun.

Three days later there was no dyspnœa or cyanosis; œdema less; no signs of ascites; signs of small effusions at bases; no venous engorgement; pulse-rate 102 per min.; blood-pressure 130/84 mm. Hg; apex-beat had retracted 1 in.; gallop rhythm less definite.

CASE 6.—A male civilian, aged 35. Shortly after liberation his ankles began to swell. Three days before admission he felt well but awoke during the night with breathlessness.

On examination: dyspnœic at rest; cyanosed. Gross œdema of legs and feet; neck veins engorged. Pulse-rate 110 per min. (regular); heart enlarged; sounds of poor quality; diastolic murmur heard all over precordium. Intravenous thiamine begun.

Three days later there was no dyspnœa or cyanosis; œdema less; pulse-rate 98 per min.; apex-beat had retracted about 1 in.; sounds of better quality.

In the other groups tachycardia was a constant feature. It was sometimes accompanied or followed by altered heart sounds—a broadened or split first sound at the apex, and less often a split pulmonary second sound. A precordial systolic bruit was sometimes heard. In severe cases the apex-beat was commonly found outside the midclavicular line.

In the severely emaciated cases blood-pressure was usually subnormal. A few patients collapsed suddenly during apparent recovery. Here the blood-pressure *fell*, but it returned to normal in about half an hour, though the patient remained only partly conscious and looked extremely weak, with slate-coloured complexion and cold sometimes cyanosed extremities with contracted veins and arteries.

There were 3 cases in middle-aged men where collapse was associated with a pronounced rise in blood-pressure, in one case to 220/110 mm. Hg. They all recovered in 10–17 days. In 2 of these cases albumin and microscopic blood and hyaline casts appeared in the urine after the collapse, but disappeared in a few days. In the same 2 cases the apex-beat moved out to the anterior axillary line, and attacks of pulmonary œdema came on nightly. There was no engorgement of the neck veins, but œdema increased during the attacks. Both patients had received daily large doses of thiamine for more than two weeks before the attack. All 3 completely recovered.

In the commoner form of collapse, with subnormal blood-pressure, respirations were slow and shallow, except when there was œdema of the lungs.

Unexplained Tachycardia.—Among the 577 cases of malnutrition there were 58 cases of tachycardia which did not respond to thiamine and for which no cause could be found (*not all had chest radiograms taken*). Most of these cases had no history of recent sore throat, tropical ulcer, *or scrotitis*. There was no significant association between tachycardia and neurological signs (table I) nor between tachycardia and tropical ulcer (table II).

It therefore seemed unlikely that these cases of tachycardia were diphtheritic. There was often some pyrexia, ordinary methods of examination. In the most advanced cases the pupils were dilated and reacted sluggishly to light, and contraction was ill-sustained.

Ophthalmoscopic appearances included normal disks even in some severe cases; temporal pallor exceeding normal limits in most cases; and signs of complete optic atrophy in a few cases. In all the advanced cases and in some of the less advanced a central or paracentral scotoma was found.

A weakness in accommodation and premature presbyopia, without evidence of refractile change in the lens, were noted in many of these cases and in patients without amblyopia.

RIBOFLAVIN DEFICIENCY

Manifestations of riboflavin deficiency were transitory, lasting about 4–8 days. Angular stomatitis was the commonest; next came magenta tongue; and cheilosis was occasionally seen. These signs were usually present singly.

Except for a few cases in which signs appeared unexpectedly late, and then usually after an attack of malaria, dysentery, or some digestive disorder, nearly all were seen within the first fourteen days in hospital. A history of signs appearing shortly after going on to a diet of higher calorie and carbohydrate value was usual.

SKIN LESIONS

Hyperkeratosis was the commonest skin lesion seen. The most common sites were round the ankles, on the backs of the hands, and round the elbows and knees. Hyperpigmentation was often present but not excessive. Underlying erythema was not seen. Itching was commonly absent and never a prominent feature. In cases with much hyperkeratosis, diarrhœa was also present in about half, and a sore red tongue in about a third. On hospital diet and nicotinic-acid therapy (average dose 300 mg. daily) the skin lesions recovered in 10–21 days. Sore tongue and diarrhœa, when present, responded more rapidly than did the skin lesions.

Dry Skin.—A dry thin scaly skin was commonly seen in the most severe cases of malnutrition. The condition was most pronounced on the lower abdomen, thighs, and forearms; often a mosaic pattern could be seen. It responded very slowly to routine treatment and to large doses of nicotinic acid. In the few cases tried, an improvement followed the giving of a fat-soluble vitamin preparation.

Scrotal Lesions.—These were never seen alone but in combination with hyperkeratosis or dry skin. In some cases the scrotum was thickened, wrinkled, scaly, and hyperpigmented. In others the scrotum was reddened, with a translucent appearance, and was partly covered with scales; these changes were seen when the scrotum was distended with œdema fluid. Itching was common in both types of scrotal lesion.

TONGUE LESIONS

Lesions on the tongue were common during the first fourteen days in hospital. They could be classified as follows:

(1) *Sore tongues* were usually reddened, often at the edges and tip, less often all over. Diarrhœa and hyperkeratosis were sometimes present. The soreness responded to nicotinic acid in 4–10 days.

(2) *Pale atrophic tongues* were always associated with anæmia and responded slowly to treatment.

(3) *Red atrophic tongues* were also found in association with anæmia, and were occasionally painful.

(4) *Magenta tongues* were seen in riboflavin deficiency (see above).

NEUROLOGICAL FINDINGS

Neurological signs attributable to malnutrition were seen in 170 cases. Their association with amblyopia, tropical ulcer, and unexplained tachycardia (see below) was tested. The results are shown in table I.

Price (1946), discussing allied prisoners-of-war and internees, remarks that "jungle sores" were common among his cases and some of these were infected with the Klebs-Löffler bacillus, which had caused a peripheral neuritis. None of our cases swabbed was found to be thus infected, and there was no significant association between neurological signs and tropical ulcer, unexplained tachycardia, or amblyopia.

Clinical findings were extremely varied. When the onset was gradual, the neurological symptoms usually began with paræsthesiæ followed by increasing weakness in the legs. Loss of balance, especially in the dark, was sometimes noted. A sudden onset with much weakness in the legs developing within 24 hours was common. In most of these patients there was little or no complaint of weakness, though there was sometimes a history of previous weakness. On examination, absent or diminished ankle jerks, with or without areas of sensory loss to pinprick, commonly of glove or stocking distribution, were found.

TABLE I—ASSOCIATION OF NEUROLOGICAL SIGNS WITH AMBLYOPIA, UNEXPLAINED TACHYCARDIA, AND TROPICAL ULCER

—	Cases of severe malnutrition			Remarks
	Neurological signs		Total	
	With	Without		
Amblyopia—	%	%	%	
With	13 (*7·65*)	35 (*8·60*)	48 (*8·32*)	p–p′ = −0·95

Totals ..	170	407	577	Not signif

Physical examination of the more severe cases showed a dissociated sensory loss. Loss to touch was uncommon; the most extensive area found was a band about 4 in. wide round both ankles. Loss of discrimination between heat and cold was present in 4 out of 5 patients examined who had extensive loss of sensation to pinprick. In 3 cases the distribution was an irregular band round the ankles, and in 1 case a large area, roughly symmetrical over the anterolateral aspect of the lower half of the thighs and anterior aspects of the legs. Loss of joint sense and some ataxia were common. The legs were more often and more severely affected than the arms. Loss of sensation to pinprick was sometimes very extensive, and in 2 cases analgesia was present over the whole skin surface; both were patients judged to have well-balanced personalities and in whom no confirmatory hysterical stigmata could be found. Vibration sense was not tested. Loss of power was affected most commonly and most severely in the following muscles in descending order: peroneal group, flexor digitorum, tibialis anticus, quadriceps femoris, and flexor hallucis. Roughly speaking, in the legs and arms, the distal muscles showed weakness first. The affected muscles were hypotonic. Tendon reflexes were either normal, diminished, or absent.

CASE 3.—A civil policeman, aged 32, had been interned at Singapore in February, 1942. Eighteen months before admission to hospital he had noted pins-and-needles in the feet and hands, and weakness in the legs. Later he noted that he was unsteady on his feet and staggered in the dark.

Symptoms continued with intermissions until shortly after the capitulation, when the rice ration was increased. He then became unable to walk. From Sept. 9 to 12 he was given every day 40 mg. of thiamine intramuscularly and 6 compound vitamin tablets by mouth.

quate owing to shortage of drugs and lack of hospital accommodation.

It is therefore surprising that out of 577 cases of malnutrition, 39 of whom developed malaria in hospital, only 21 (3·6%) were recorded as having palpable spleens. This was commented on by several medical officers in charge of wards and splenic enlargement was specially looked for.

PULMONARY TUBERCULOSIS

Of 30 patients admitted with pulmonary tuberculosis, 28 had positive sputum, 25 had bilateral disease, 6 had clear pleural effusions, 1 had a tuberculous total pyopneumothorax, 4 had extensive tuberculosis of the larynx, epiglottis, and tonsillar regions. A few others had a mild chronic non-specific laryngitis.

Three cases were afebrile on a routine of being "up" for two hours daily; the others were all bed patients. The bed patients, classified according to the symptoms and the anatomical extent of the disease, consisted of 12 moderate cases, 6 severe cases, and 9 hopelessly advanced cases (4 of whom died in hospital).

Since the patients were to be evacuated within a week or two, no active collapse therapy was given, except in one case to refill a successful artificial pneumothorax initiated five months earlier in the camp hospital. The tuberculous pyopneumothorax and two of the effusions were aspirated, diagnostic puncture alone being carried out on the others.

These men all showed some malnutrition, but this improved rapidly on the routine treatment, despite the presence of tuberculosis, except in the most extensive cases.

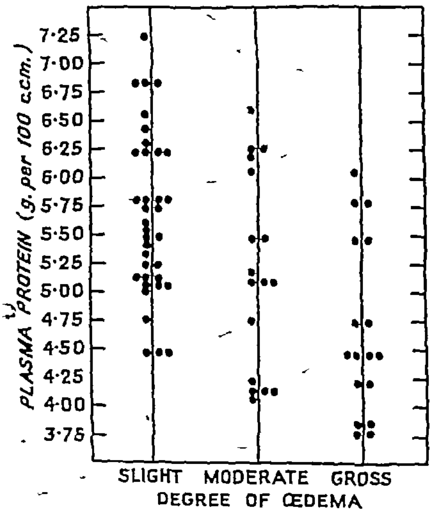

Fig. 1—Plasma-protein levels in 70 cases of œdema.

More than two-thirds of the cases gave a history of illness, referable to the chest, of less than nine months' duration, though the stage of the disease was, on the average, advanced. This suggests that malnutrition hastened the course of tuberculosis.

CAUSES OF DEATH

The causes of all deaths taking place between Sept. 9 and Nov. 30, 1945, were as follows:

Cause of death	*Cases*
Malnutrition and beriberi	8*
Empyema and malnutrition	1
Abscess of right thigh and beriberi	1
Effects of head injury and malnutrition ..	1
Cirrhosis of the liver and malnutrition .	1*
M.T. malaria and malnutrition	1
Intestinal obstruction and malnutrition ..	1
Pulmonary tuberculosis and malnutrition ..	4
Carcinoma of lung	1
Coronary artery thrombosis	1
Syphilitic aortitis	1

* Includes the 2 patients who died after plasma infusion.

Necropsies were made in all cases except 1 of malnutrition and beriberi and the 4 cases of pulmonary tuberculosis.

TREATMENT OF MALNUTRITION

Rest.—Patients remained in bed until ordered up by the doctor. This was not always easy to enforce, since after more than three years' captivity the men naturally wanted to be up and about. Slight œdema of the ankles, sore tongue, angular stomatitis, weakness of the legs, and residual signs of peripheral neuritis were not considered to be indications for rest in bed. The *nurses* were instructed to put to bed at once any patient found to have a rapid pulse. This was considered to be an important indication for rest in bed. Fever, worsening of the general condition, increasing signs of vitamin deficiency, diarrhœa, and dyspepsia were some of the other indications. Tachycardia at rest, breathlessness, palpitations, and precordial pain, a rising or falling blood-pressure, or any signs of collapse were thought to be indications for absolute rest.

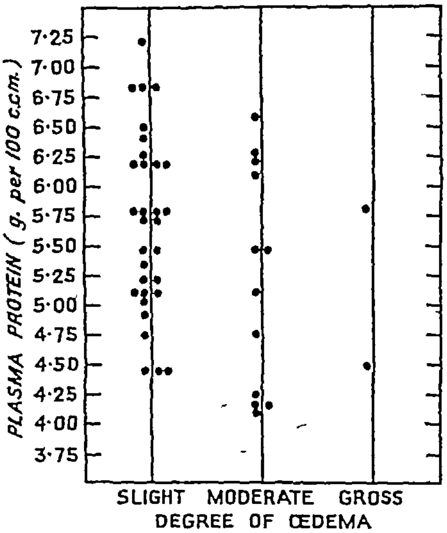

Fig. 2—Plasma-protein levels in 45 cases of œdema in which knee and ankle jerks were present.

Nursing.—An adequate and efficient nursing staff was looked upon as an important factor in the successful treatment of malnutrition. Secondary factors related to nursing efficiency, such as ward domestic staff, equipment, amenities, food-service, heating, lighting, and water-supply, were almost as important. If these were inefficient the sisters had less *time for the patients.*

At first a large proportion of the patients had diarrhœa, and some of these were incontinent. Bedpans had to be cleaned quickly, and there was no time for proper disinfection. No ill effects could be traced to this procedure. Bedding had often to be changed. In some wards tow and cotton-wool and sanitary towels were used to save bedding. Bedsores were the rule among the more severe cases. They were usually present on admission, but a few developed in hospital. Mouths needed a good deal of attention, for dry mouths with dry fissured tongue and dirty teeth were common.

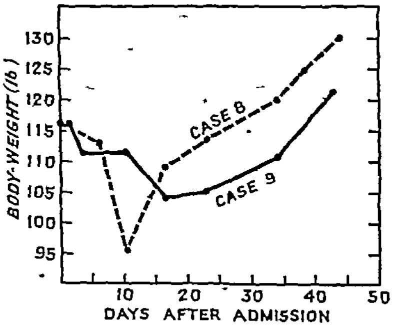

Fig. 3—Examples of initial loss of weight of œdematous patients on admission to hospital. Case 8's pre-war weight was 162 lb. and case 9's 152 lb. Initial loss of weight is due to loss of œdema fluid.

By Sept. 20 most of the wards were preparing milk drinks and could do simple invalid cooking in the ward kitchens. The graduated malnutrition diets I, II, and III (table III) were prepared in the wards. The severe cases required individual feeding. This was time-but no symptoms of fever. This form of tachycardia and pyrexia was not seen during the period of captivity in a hospital which served a camp holding on the average 12,000 men (E. K. Cruickshank, personal communication). Manson-Bahr (1945), however, remarks that an irregular pyrexia, seldom exceeding 100° F, has been noted in some epidemic outbreaks of beriberi. The tachycardia and fever often persisted though signs of vitamin deficiency disappeared or improved, and the patient put on weight and in every other way appeared to be progressing satisfactorily.

TABLE II—ASSOCIATION OF UNEXPLAINED TACHYCARDIA WITH TROPICAL ULCER

—		Cases of severe malnutrition		
		Tachycardia		Total
		With	Without	
Tropical ulcer	With	3 (*5·2%*)	43 (*8·3%*)	46 (*8·0%*)
	Without	55 (*94·8%*)	476 (*91·7%*)	531 (*92·0%*)
Totals		58	519	577

There was sometimes a history of breathlessness on exertion, or fatigue, and a few patients complained of attacks of faintness and palpitations. It was among such cases that the collapsed state, previously referred to, was liable to occur.

CASE 7.—A lance-sergeant, aged 35, was admitted as an ambulant case. He was very thin, with œdema of the ankles, and took his food well. Three days later his morning pulse-rate was 98 per min., and he was ordered to bed. During the afternoon, while walking, he had sudden severe dyspnœa and collapsed.

On examination half an hour later he was cyanosed, feebly fighting for breath, and coughing up watery sputum, with thready and irregular pulse, contracted veins, and cold extremities. Split first sound at apex. Except for left pectoral region, percussion note impaired at all areas; air entry greatly reduced; many bubbling sounds. Thiamine and nikethamide were injected intravenously, and oxygen was given. After half an hour his pulse and colour improved and respiratory efforts became more vigorous. Œdema developed rapidly up to the costal margins. Above the œdema he appeared dehydrated.

Next day he looked worse, being exhausted, with ashy complexion, and signs as on previous day. An hour later he was reported to be failing rapidly; but, when seen half an hour later, the difference in his appearance was striking. He was sleeping quietly, with normal colour, less œdema, and few râles at bases; tachycardia and altered heart sounds still present.

Six days later a relapse coincided with an attack of lobar pneumonia. He was treated with penicillin and recovered slowly.

ŒDEMA

In most cases œdema was postural, but in recently admitted patients pretibial œdema which was not postural was sometimes seen. The œdema which persisted was always postural. In the grossly œdematous the œdema often extended to the chest wall and was often accompanied by effusions into the knee-joints, ascites, and bilateral pleural effusions. A few cases of pericardial effusion were seen. Œdema often increased or appeared after admission to hospital. It was suggested that a normal salt intake following a long period on reduced intake was a contributory cause of this œdema. Œdema sometimes decreased during an attack of diarrhœa or a fever; occasionally it increased during a fever. Gross œdema was present in both cases showing venous engorgement (cases 5 and 6). Left ventricular failure sometimes developed in patients without œdema. In 3 cases albumin, microscopic blood, and scanty leucocytes and hyaline casts appeared in the urine, but the appearance was transitory and did not correspond with change in the œdema.

Plasma Proteins.—Total plasma-protein estimations were done in 70 œdematous cases (fig. 1). Though low readings were common in the grossly and moderately œdematous, and higher in the slightly œdematous, the levels were sometimes higher in the grossly œdematous than in the slightly œdematous. There was therefore no significant trend in the level of plasma protein with increasing degrees of œdema in these cases. This statement holds good for cases in which knee and ankle jerks were present (fig. 2). For diagnosis plasma-protein estimations, considered alone, seem to be of little value. The absence of any close relation between œdema and plasma-protein levels was also noted in cases of starvation in Europe (Mollison 1946). Unfortunately it was impossible to have serum-albumin and serum-globulin estimations done.

Loss and Gain of Weight.—Twenty-two patients, 6 of whom had slight œdema and 8 moderate œdema, were weighed at weekly intervals. In all but one the œdema was judged to be less or to have disappeared at the end of two weeks. The results were as follows:

Average weight (lb.)		*Average loss (lb.)*	*Average gain (lb.)*	
Before capture	*On admission*	*during internment*	*1st week*	*2nd week*
155	120	35	$5^1/_2$	5

In another series, where weight lost during internment was calculated from the lowest weight in hospital, the average loss was 41 lb. With more extensive œdema there was usually an initial loss of weight. Fig. 3 shows examples of this in cases 8 and 9.

DYSENTERY AND DIARRHŒA

Dysentery or diarrhœa was the reason for the admission of 87 patients to hospital. Besides these, 133 of the 577 cases admitted primarily for malnutrition had diarrhœa, and some of them were transferred to the dysentery ward. Of 115 patients from the dysentery ward 19 had amœbic dysentery; 1 amœbic hepatitis; 21 clinical dysentery; 18 infective diarrhœa; 49 dietetic diarrhœa; 3 giardiasis; and 1 colitis.

Some cases of amœbic dysentery were resistant to emetine; over the previous three years they had had ten or more courses of emetine.

Clinical dysenteries had blood and mucus in the stools, infective diarrhœas had not; both responded to sulphaguanidine. Dietetic diarrhœas often started soon after the increase in rations; they did not respond to sulphaguanidine, but did respond to restriction of diet. Several of these patients had sore red tongues and showed an initial improvement on nicotinic acid, but dietetic restriction was usually needed also.

Only one case of sprue was seen.

MALARIA

The incidence of the various types of malaria was as follows:

Type	*Admitted primarily for—*		
	Malaria	*Malnutrition*	*Other disease*
Benign tertian	32	20	1
Malignant tertian	7	3	0
Combined	1	1	0
Clinical malaria	28	15	1
Blackwater fever	1	0	0
Effects of malaria	4	0	0
Totals (114)	73	39	2

An attack of malaria in a patient with severe malnutrition was nearly always a cause for anxiety until the fever was controlled. In most cases progress from malnutrition was set back considerably and there was a loss in weight of half a stone and sometimes much more.

Many patients with and without malaria gave a history of repeated attacks of fever, some of which were proved cases of malaria. Sometimes treatment had been inade-

CASE 15.—This man was admitted to a camp hospital on August 16, 1945, with a diagnosis of beriberi and ulcers of the feet. Since then he had passed watery stools, about 18 daily, until Sept. 17, when the diarrhœa began to improve. He had had frequent attacks of flatulence and of feeling " blown up " after meals; this had become more severe since Sept. 17, and made him afraid to eat; previously he had been eating all his food.

On examination (Sept. 20) he was emaciated, with gross œdema, ascites, and bilateral pleural effusions. Mucosæ pale; tongue reddened at edges and tip. Pulse-rate 100 per min. Ankle jerks absent: areas of analgesia and paresis of legs with much hypotonia. Diarrhœa returned, and he had lost all desire for food.

After four days' of graduated diet the appetite had returned and the diarrhœa was considerably improved. He still complained of abdominal distension and discomfort, which was relieved by tapping the ascites.

Improvement continued until Oct. 8, when he had a further attack of distension and flatulence. The diet was reduced to less than 2000 calories, with relief of symptoms.

CASE 16.—Towards the end of July, 1945, this man had been admitted to a camp hospital as a case of beriberi and tropical ulcers. On August 20, 1945, there was a considerable increase in the diet. On the 25th he started passing frequent watery stools. After a course of sulphaguanidine there was some improvement. On Sept. 19 the diarrhœa became much worse and was accompanied by loss of appetite, flatulence, and distension.

On examination (Sept. 19) he was very wasted and mentally depressed, with extensive paresis and analgesia of legs and loss of knee and ankle jerks. Pulse-rate 118 per min. Blood-pressure 124/92 mm. Hg. Split first sound heard at the apex. Extremities cold. Petechial rash on forearms. Eight watery motions in the past twenty-four hours, appetite very poor; complained of acid eructations and distension.

After three days' graduated diet the dyspeptic symptoms had disappeared and the mental depression had gone.

CASE 17.—After a reduction in the camp rations in June, 1945, this man began rapidly to lose weight and complained of generalised weakness, especially in the legs. Later his feet began to swell. On August 1, 1945, he was admitted to a camp hospital. On the 20th the rations were considerably increased, and about a week later he complained of a sore tongue and diarrhœa, which had continued.

On examination (Sept. 20) he was emaciated, with dry and scaly skin, red and painful tongue. He was drowsy and apathetic. Some œdema of the ankles and signs of bilateral pleural effusions. Much generalised weakness. Loss of joint sense in great toes. Paresis of legs. Knee jerks absent. Much hypotonia of muscles. Tachycardia. Watery stools, 8 in the past twenty-four hours.

After three days' graduated diet 2 motions had been passed in twenty-four hours, appetite had returned, and mentality was much brighter.

These patients made satisfactory progress and were evacuated by hospital ship on Oct. 22.

Relapses following an initial improvement were common, but nearly always responded to further reduction in diet. It was easily possible to be misled by the patients' frequent demands for more food. Several patients succeeded in persuading the Chinese ward orderlies to buy them extra food, in spite of having been warned against overeating. One patient, who became severely ill and collapsed for no apparent reason, was found to have in his locker a large quantity of noodles and other forbidden food. He later admitted having eaten, earlier in the day, several large helpings of noodles.

In the following case the patient suddenly collapsed and died after an initial improvement. It was thought that the sudden increase in diet was a contributory cause of death.

CASE 18.—A man had had diarrhœa for ten weeks before admission. It began with flatulence and distension. During this period he gradually lost his appetite. Six weeks previously he noted in his right thigh a lump which gradually became bigger.

On examination (Sept. 19) he was extremely emaciated and lethargic. It took several minutes to rouse him sufficiently to answer questions; then he spoke very slowly in a monotonous voice. Face expressionless. Extensive dry hyperkeratosis of skin. Tongue and mouth dry. Slight œdema of ankles. Fluctulant swelling about 12 in. long in right thigh. Pulse-rate 80 per min. Blood-pressure 116/70 mm. Hg. Heart normal. Abdomen scaphoid. Pallor of temporal disks. No reaction to pinprick except over face. Tendon reflexes normal. Incontinence of fæces and urine. All food refused.

On Sept. 22 a Ryle tube was passed, and the graduated diet given through it. Pus was aspirated from the abscess in the right thigh and penicillin 200,000 units inserted.

Sept. 30: no incontinence; bowels opened 3 times in twenty-four hours; patient enjoying his food and talking to his neighbours; pulse-rate 120 per min.; temperature 102° F; no signs of abscess in the thigh.

The rapid pulse and fever continued until Oct. 3, when at 6 A.M., while being washed, he suddenly collapsed, dying five hours later.

At necropsy all the organs were small (heart 200 g., liver 850 g., kidneys 200 g., spleen 110 g.). The lungs were œdematous, and the mucosa of the stomach and intestines looked atrophic.

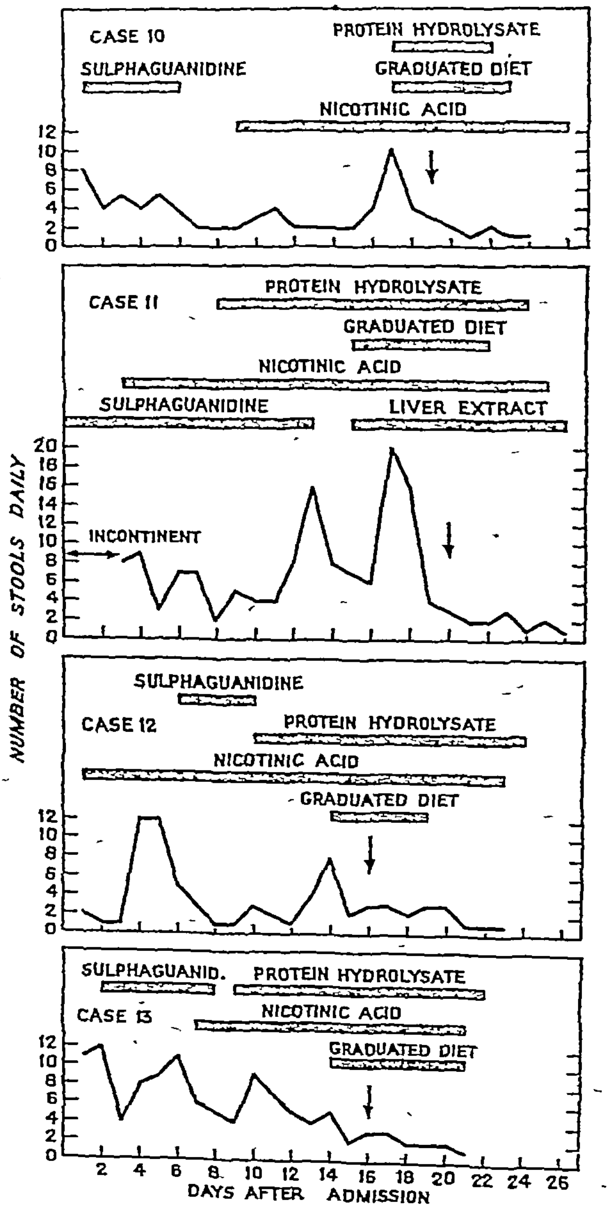

Fig. 4—Analysis of treatment in cases 10–13, showing that, of the different forms of treatment, restriction of diet bore the most constant relationship to improvement. (The vertical arrow marks the appearance of solid stools.)

TABLE III—GRADUATED DIETS FOR SEVERE MALNUTRITION WITH ANOREXIA AND/OR DIARRHŒA

Diet	Details and instructions	Total fluid (oz.) for non-œdematous cases	Total fluid (oz.) for œdematous cases	Fats (g.)	Carbohydrates (g.)	Proteins (g.)	Calories	Non-fat calories
I	Protein hydrolysate; give 3 oz. two-hourly for 7 feeds. For one day	31	21	0	30	15	180	180
II	Protein hydrolysate; give 4 oz. two-hourly for 7 feeds, each feed followed by egg-and-milk mixture. (Total daily milk mixture: condensed milk 1 pint, two beaten eggs, and 1 oz. of sugar; add $^1/_2$ pint of water for non-œdematous cases.) Continue until the appetite returns	57	47	60	134	76	1380	840
III	Egg-and-milk mixture three-hourly for 6 feeds. Rolled oats 2 oz., tinned fruit 2 oz., tinned chicken 4 oz. daily. (Total daily milk mixture: condensed milk $1^1/_2$ pints, two beaten eggs, and 2 oz. of sugar; add $^1/_2$ pint of water for non-œdematous cases.) Continue for at least three days	68	58	96	170	99	1940	1076
IV	Hospital light diet	80	60	136	412	128	3384	2160
V	Hospital ordinary diet	Ad lib.	Ad lib.	200	495	120	4260	2460

consuming, and during the rush period the sisters had little time for it. Some of the fitter patients and a few volunteer workers who became attached to the ward staff gave valuable help in this work. Fluid charts were often kept by the patient or by one of his fitter neighbours.

Diet.—In the case of the hospital ordinary and light diets (table III) four meals were served daily; and, between meals, milk drinks with biscuits, sweets, or chocolates were given. All patients were given 6 compound vitamin tablets daily. To patients with diarrhœa, the tablets were given as an emulsion. 'Marmite' or vegamite was given ad lib. to all patients except those few who disliked them.

Most of the mildly ill patients took these diets without any ill effects, but among moderately or severely ill patients disorders attributed to overfeeding were common. Except for the most severe cases with anorexia, a very large appetite, which was not satisfied by these diets, was the rule. It was evident that in some cases control of diet was important.

The graduated diets shown in table III were used in the severe cases or in cases where it was thought that symptoms were due to overfeeding. Some patients found these diets distasteful, but in those wards where something of the rationale of the treatment was explained to the patients there were no complaints and the best results were achieved.

Overfeeding was often followed by flatulence and abdominal distension, with or without diarrhœa. This usually caused considerable discomfort lasting from a few hours to a few days, but in the more severe cases the digestive disorder was sometimes accompanied by weakness and a rapid feeble pulse, and several cases of sudden collapse, with low blood-pressure, rapid pulse, cold extremities, and stupor were attributed to overeating.

TREATMENT OF DIARRHŒA

Some patients with diarrhœa improved rapidly after being in hospital for three or four days; some of these had signs of nicotinic-acid deficiency. Cases of severe diarrhœa or mild diarrhœa which did not improve within two or three days were treated with a kaolin mixture or sulphaguanidine. Wet-film examinations of stools were made, and any protozoal infections found received appropriate treatment.

Patients who continued to have diarrhœa (there were many such) gradually improved over a period ranging from about six days to four or more weeks. In these cases, if the diet was drastically reduced, or if the graduated diet was given, improvement usually took place in a few days. Some patients who were later diagnosed as having nutritional diarrhœa showed a transient improvement while taking sulphaguanidine.

Several forms of treatment were used simultaneously in nearly all the cases, so it was not always clear which had been responsible for improvement, unless treatment was analysed more closely. Fig. 4 shows cases 10–13 analysed from this aspect. It is fairly clear that restriction of diet bears the most constant relationship to improvement.

Severe Cases.—The presence of anorexia, lethargy, and diarrhœa demanded a great deal of nursing. The persistence and tact needed in persuading the patient to take his two-hourly feeds was often rewarded by the mitigation of these symptoms in three to five days. Later attention was directed to continuing absolute rest and restricting diet.

Illustrative Cases.—The following patients were treated in hospital for five to twelve days before being given the graduated diet. During this time they received compound vitamin tablets 6 daily, nicotinic-acid tablets 3–6 daily, parenteral thiamine 5–10 mg. daily, and a course of sulphaguanidine. They were on the hospital light diet but were reported as being very difficult to feed; the exact proportion of the diet taken during this time was unknown. In 2 cases there was a transient reduction in the number of daily motions while on sulphaguanidine, but over the period their condition had generally deteriorated. On Sept. 22 they were put on the graduated diet.

CASE 14.—A man with a year's history of weakness and numbness of the feet was admitted to a camp hospital on August 27, 1945, with great weakness of the legs and diarrhœa.

TABLE IV—RESULTS OF TREATMENT IN 40 CASES OF ŒDEMA

Treatment	Signs of neuritis	Good response	Delayed response	No response
No extra treatment	With	0	2	3
	Without	0	3	2
Thiamine 10–20 mg. daily parenterally	With	4	6	5
	Without	1	0	2
Thiamine as above and 'Neptal' 1 or 2 c.cm. given 2 or 3 times	With	5*	3	1
	Without	2	1	1

* The reduction in œdema in these 5 cases followed a profuse diuresis, which occurred soon after the giving of neptal.

On examination (Sept. 21) he was emaciated, drowsy, and apathetic, passing watery motions about 10 times daily. No appetite. Extreme general weakness. Knee and ankle jerks absent; areas of analgesia and partial paresis of legs, with much hypotonia. Mucosæ pale. Pale smooth tongue. Much œdema of legs. Signs of ascites, and bilateral pleural effusions present.

After three days' graduated diet there was much improvement. Appetite had returned, mentality was much brighter, and motions were semi-formed and reduced to 3 daily.

in general. Before its significance in this respect can be studied directly it is necessary to gain further information as to the nature of the stimuli which cause fibrinolytic activity in the living human subject. This paper records some preliminary attempts to identify the disturbing conditions which have this effect.

METHOD OF DEMONSTRATING FIBRINOLYTIC ACTIVITY

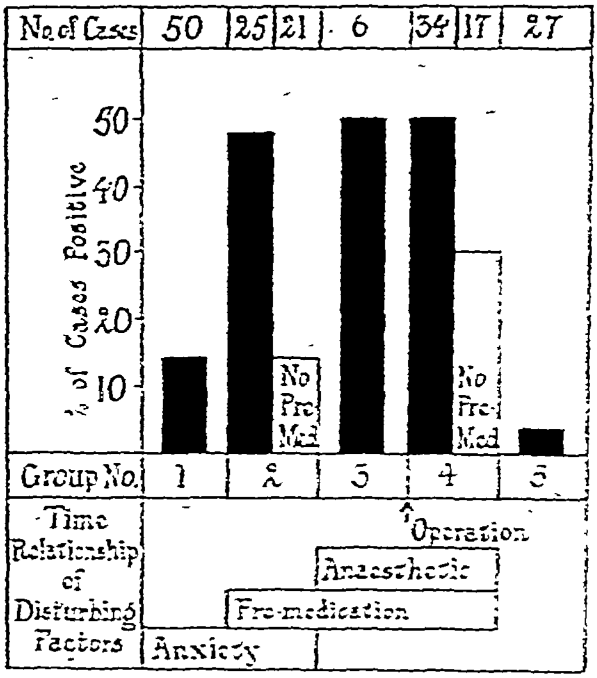
A modification of the method described by Macfarlane (1937) was used, which depends on the fact that dilution favours the dissociation of the normal plasma-antiplasmin (enzyme-inhibitor) complex, so that potential increases in activity not demonstrable in whole blood become apparent.

Blood was taken by venepuncture, mixed with a ninth of its volume of 3·8% sodium citrate, and spun at 2500 r.p.m. for 10 minutes. The plasma was separated and was then diluted 1 in 16, 1 in 32, and 1 in 64, using (*a*) 0·035% $CaCl_2$, and (*b*) 1/250 thrombin ('Clotting Globulin,' Lederle) both made up in the buffer-merthiolate-saline diluent already described (Macfarlane and Pilling 1946). The final volume of the dilutions was 3 ml. contained in Wassermann tubes which were incubated at 37° C. Clotting occurred rapidly in the thrombin preparations, and in a few minutes in the recalcified plasma dilutions, and in all was sufficiently firm to allow inversion without spilling, with the occasional exception of the 1/64 dilutions. After 24 hours' incubation the tubes were inspected for fibrinolysis, indicated by the disappearance of the clot. In general, the higher dilutions were more sensitive than the lower, and the thrombin-clotted plasma than the recalcified. A weak reaction would be indicated by lysis in the 1/64 dilution of the thrombin preparation in 24 hours, a strong one by the disappearance of fibrin in all six tubes in a few hours. In this paper, however, no attempt is made to analyse the results quantitatively, a positive result being recorded if all fibrin had disappeared from one or more dilutions within 24 hours.

RESULTS

A. *Normal Controls.*—It was necessary first of all to determine the results obtainable on normal blood by the method described, so 70 blood samples from 54 normal volunteers (students and medical staff) were examined. A weak positive reaction was obtained in the case of one student on one occasion: in all other samples no fibrinolysis occurred. In view of Willson and Munnell's (1946) observations relating to pregnancy, a large number (137) of normal pregnant women at various stages of gestation were examined; all were negative. In 4 normal volunteers blood taken during menstruation showed no fibrinolytic activity. From these findings it was considered that the method described is unlikely to give positive results under normal conditions.

B. *Patients Undergoing Surgical Operation.*—In previous studies of postoperative fibrinolysis too few blood samples were obtained from each patient to allow analysis of the possible effect of the various factors involved by a surgical operation. The most obvious of these are, in order of time, (*a*) the condition for which the patient is to be treated, (*b*) fear of the operation, (*c*) premedication, (*d*) anæsthesia, and (*e*) such results of surgery as trauma, shock, and hæmorrhage. In an attempt to analyse the possible effect of these multiple factors blood samples were taken (1) on the day before operation, (2) after premedication, (3) after anæsthetisation, (4) immediately after operation, and (5) on the following day, in a series of 34 patients undergoing operation for a variety of conditions. Not all blood samples were taken in all cases, but sufficient were obtained in each time-group to allow comparison of results, with the exception of group 3 in which only 6 cases were examined. In these 34 cases, 88 observations were negative and 36 positive. There was no apparent correlation with age or sex. The percentage of positive results in each group is indicated by the black columns of the histogram (see figure) related to the probable effective period of the factors under consideration. Group 1 also includes 18 patients of a second series described later.



Incidence of fibrinolysis in patients (1) the day before operation, (2) after premedication, (3) after anæsthetisation, (4) immediately after operation, and (5) the day after operation. The white columns refer to patients not receiving premedication.

It will be seen from these results that the occurrence of postoperative fibrinolysis is confirmed, 50% of positive results being recorded in group 4. A considerable proportion of patients showing fibrinolysis in this group, however, had undergone only the most minor physical trauma, such as cystoscopy, ureteric catheterisation, sigmoidoscopy, or injection of hæmorrhoids. A more remarkable finding, perhaps, is that the incidence of fibrinolysis is almost equally great in group 2, before the operation or anæsthetic, a result that invalidates any supposition that these latter factors are the major causes of postoperative fibrinolysis. Disturbances occurring during the preoperative period must be at least equally potent. Of the 17 patients giving positive postoperative results, 9 were also positive before operation.

The conditions for which the patients were treated did not appear to provide a likely explanation of these findings. No particular type of abnormality was associated with preoperative fibrinolysis, which occurred, in fact, in patients with complaints no more serious than ingrowing toenail, hæmorrhoids, or herniæ; in a man admitted for circumcision, and in a woman for an examination of the uterus that showed no abnormality. Moreover, 19 of the patients giving positive results in groups 1–4 were investigated on the day after operation and all had then become negative with the exception of one following circumcision.

The effect of *premedication* was next investigated. Of the patients examined in groups 2 and 3, 31 had received morphine (gr. 1/6–1/4) and atropine (gr. 1/100) except 4 who had received 'Omnopon' instead of morphine, a substitution that did not affect the incidence of fibrinolysis. In a further series of 21 patients, however, premedication was withheld, and the results for these in groups 2 and 4 are indicated in the histogram by white columns. It will be seen that, when premedication is omitted, there is a considerable reduction in the incidence

TREATMENT OF ŒDEMA

The response to treatment of 40 unselected cases of œdema is given in table IV.

After intravenous neptal a diuresis of 180 oz. or more of urine passed in twenty-four hours was fairly common. Diuresis following thiamine or intravenous plasma was sometimes accompanied by profuse watery diarrhœa.

Reconstituted Plasma Therapy.—Intravenous reconstituted plasma was given in a few cases of persistent œdema. On 3 occasions severe pulmonary œdema developed ; 2 of these cases were fatal. In 1 of the fatal cases double-strength plasma was given at the rate of a pint in twelve hours. In this case advanced cirrhosis of the liver and a pale flabby heart weighing only 160 g. were found at necropsy. The other fatal case received a pint of normal-strength reconstituted plasma in two hours, followed by 3 oz. of double-strength plasma given in two hours. Necropsy showed œdema of lungs and brain. The heart weighed 230 g., and the myocardium had a normal appearance. For several hours before death this patient was incontinent of urine and fæces, and passed large quantities of urine and watery stools ; during this time the subcutaneous œdema and ascites decreased appreciably.

In 2 very œdematous cases, where plasma-protein estimations were done before and after plasma infusion, the level fell though the œdema was less. In a third case, with very slight œdema, the plasma-protein level rose. Alteration in the albumin/globulin ratio would explain this apparent discrepancy.

Blood-transfusion was tried in some cases with severe anæmia, but was given up owing to the high incidence of reactions.

SUPPLEMENTARY TREATMENT

Nicotinic-acid tablets, each containing 50 mg., were used in patients with pellagrous dermatitis, sore red tongues, scrotal lesions, or diarrhœa. The dose given was 50–150 mg. three times a day by mouth, or 50–100 mg. three times a day intramuscularly. Nikethamide was also used in doses of 1 or 2 c.cm. twice daily intravenously.

There were no definite indications for giving ascorbic acid, but it was sometimes used—e.g., in patients with tropical ulcers and bedsores—in doses of 50–150 mg. three times a day by mouth.

Vitaminised oil, 1 drachm three times a day, and a proprietary preparation in capsules, each containing 4000 I.U. of vitamin A and 400 I.U. of vitamin D, were given to some patients with dry skins.

The average daily dose of sulphaguanidine was 14 g. daily.

Compound vitamin tablets, containing ascorbic acid 25 mg., nicotinic acid 10 mg., riboflavin 1 mg., and thiamine 1 mg., were often given with benerva tablets, which contained 1 mg. of thiamine.

Protein hydrolysate was given by mouth. It contained 2·5% amino-acids in 5% glucose solution.

The liver extract used contained the equivalent of $^{1}/_{2}$ lb. of fresh liver to the ounce ; the average dose was 1 oz. daily.

SUMMARY

This report deals with 1230 patients, most of whom were too ill to be evacuated in hospital ships. Their previous diet had been deficient, and they came from camps with a high incidence of disorders attributed to vitamin-B deficiency.

At least 577 were admitted primarily for malnutritional disorders. These disorders are described.

Notes on weight loss and gain, tropical ulcer, dysentery and diarrhœa, malaria, and pulmonary tuberculosis are recorded.

A summary of the causes of all deaths between Sept. 9 and Nov. 30, 1945, is given.

Good nursing was found to be the most important factor in treatment.

Though the great majority of mild and moderately ill patients could take the hospital ordinary and light diets without ill effects, the importance of controlling the diet in certain cases was emphasised. Careful dieting and individual feeding were the only effective measures in treating the most severe cases of malnutrition.

In the treatment of œdema some cases responded to thiamine. A further group of cases responded to thiamine and neptal. Other cases did not respond.

The giving of plasma and fresh blood (after cross-matching) was stopped owing to the high incidence of reactions.

The small number of deaths due to malnutrition out of a large number of dangerously ill patients reflects great credit on the nurses.

We wish to thank Major-General Sir A. Biggam and Col. (S. Musgrove, officer commanding the 47th British Gener Hospital, for their permission and encouragement in publishi this report ; those medical officers of the 47th B.G.H. whos coöperation facilitated the collection of the information whic appears in this report ; and Dr. D. D. Reid for his invaluab help with the statistical data.

OBSERVATIONS ON FIBRINOLYSIS

SPONTANEOUS ACTIVITY ASSOCIATED WITH SURGICAL OPERATIONS, TRAUMA, &C.

R. G. MACFARLANE
M.D. Lond.
RADCLIFFE LECTURER IN HÆMATOLOGY, OXFORD UNIVERSITY ; CLINICAL PATHOLOGIST

ROSEMARY BIGGS
M.B. Lond.
GRADUATE ASSISTANT, DEPARTMENT OF PATHOLOGY

RADCLIFFE INFIRMARY, OXFORD

SEVERAL workers have observed that, in variou pathological states, human blood spontaneously develop fibrinolytic activity. Yudin (1936) found that clotte blood obtained after sudden death underwent rapi liquefaction. Macfarlane (1937), using diluted recalcifie plasma, observed fibrinolysis in the blood of about 75% of patients immediately after surgical operation, a findin confirmed by Imperati (1937), though he recorded th lesser incidence of 50%. Mole (1943), working with bloo from cases of sudden death, demonstrated fibrinolysi apparently due to a proteolytic enzyme, probabl identical with that studied by Christensen and MacLeo (1945) and which they have called "plasmin." Tagno et al. (1946) recorded fibrinolytic activity in cases o severe burns, hæmorrhage, and barbiturate poisoning Willson and Munnell (1946) have reported its occurrenc in toxæmia of pregnancy and during normal menstrua tion, but their technique makes it difficult to judge th significance of their findings.

From these observations it appears that fibrinolysis occurs in association with a variety of disturbances in which the common factor is obscure, unless it be covered by that ill-defined term, "shock." The phenomenon is almost certainly due to the proteolytic digestion of fibrin resulting from activation of plasmin, a component of the enzyme system existing in normal blood discussed in a previous paper (Macfarlane and Pilling 1946). The normal function of this system is at present unknown, but its activation under the conditions mentioned suggests that it may take part in the development of "shock" and its sequelæ, or in the reactio disastrous, and some patients are put to too much emotional strain during treatment. As we are well aware, this has a deleterious effect on the progress of the disease.

Apart from surgery, the great benefits of which we do not wish to decry, the very facts of diagnosis and subsequent segregation constitute a severe threat to morale. A long stay in hospital, involving perhaps many months of rest in bed, does not tend to reinforce confidence, and sometimes creates more problems than it solves. To these emotional stresses may be added domestic and economic problems. Long rest in bed is useless without a measure of mental serenity.

With these circumstances in mind we have attempted to assist patients over crises in their treatment by giving them amphetamine sulphate ('Benzedrine'). An adequate summary of the uses of this drug, together with its indications and suggested doses, is given by Bett.[2] Doses much larger than those which we have used can be given, and no ill effects have been found when amphetamine has been administered continually for two years or more.

Amphetamine is a powerful stimulant of the central nervous system, an action which it owes to its ability to increase cerebral respiration. It produces euphoria and allays depression and fatigue, the patient becoming more alert and conscious of a feeling of well-being and increased confidence. In doses of 15 mg. by mouth amphetamine has little or no effect in raising blood-pressure or pulse-rate, though larger doses have these effects, and individual idiosyncrasy has been reported.

The drug has been used in widely different conditions but apparently not in pulmonary tuberculosis. We have used it in two ways: (1) as a short-term policy during thoracoplasty; and (2) to encourage the depressed, apathetic, or over-anxious patient.

DURING THORACOPLASTY

CASE 1.—A very apprehensive man, aged 24, developed a large extrapleural effusion after apical thoracoplasty. This led to non-closure of the wound and pyrexia. Four-hourly injections of penicillin were started, but after two days the patient had a complete "nervous breakdown," weeping and shouting when the nurse approached to give an injection or dress his wound. He protested that he could not continue the treatment and wanted to be left alone.

A course of amphetamine sulphate was started, 5 mg. (1 tablet) being given at 8 A.M. (half an hour before breakfast) and at noon (half an hour before lunch). Two hours after the first dose the patient's attitude was completely changed. He became bright and cheerful and told the doctor on his round that he felt "perfectly well" and asked when he might be allowed up.

His injections of penicillin were started again without protest and continued for nine days, when his temperature had settled and his wound healed. Amphetamine was then discontinued. The patient was "graded up" after two weeks, and three months later was back at light work

CASE 2.—A highly introspective and dejected man, aged 26, had had a total left thoracoplasty for a chronic tuberculous empyema, but after two stages he developed a bronchopleural fistula and spread of disease to the right lung. He became morbidly depressed when told that a right artificial pneumothorax should be attempted before the final stage of his thoracoplasty.

Amphetamine sulphate was given, as in case 1, for three weeks with results so beneficial that the failure to establish a right pneumothorax in no way affected his feeling of well-being. After a period of rest, during which amphetamine was discontinued without reversion to his depressed state, the third stage was performed.

A second course of amphetamine, lasting two weeks, followed this stage. An extrapleural collection of fluid eventually communicated with the bronchopleural fistula, and the patient became greatly distressed when each morning he coughed up 5 or 6 oz. of foul-tasting material.

A third course of amphetamine was given for four weeks, and this enabled him to bear his troubles with fortitude. He continued to be cheerful and did not complain of his slow progress or of his long period of complete rest in bed. His appetite improved greatly, and he gained over half a stone in a month. He is still under treatment.

CASE 3.—A man, aged 20, who had extensive tuberculous tracheobronchitis and cavitation in his left lung, was treated by pneumonectomy after two years' conservative treatment in this hospital. Postoperatively he had three-hourly injections of penicillin (given prophylactically) and aspiration of the residual pleural effusion on alternate days.

On the ninth day after operation he complained of pain at the site of injection and began displaying concern at his continued pyrexia. He was well aware of the hazards of the operation. Amphetamine sulphate was given as in the previous cases and continued for two weeks. There was an immediate cessation of pain and apprehension and thence an uninterrupted convalescence.

CASE 4.—A man, aged 30, had a partial consolidation of the right upper lobe following anterior-stage thoracoplasty. He became extremely ill, apprehensive, and uncoöperative. Amphetamine, given as before, completely changed his outlook and secured his coöperation. After two weeks the acute process had subsided and he was prepared for, and even demanding, the completion of his surgical programme.

CASE 5.—A man, aged 43, was habitually depressed and introspective. Thoracoplasty was only considered feasible in the light of our experience with amphetamine. The drug was therefore given as a routine after the first stage. His postoperative mental outlook and physical "well-being" showed a great improvement on his preoperative condition, notwithstanding the development of a large extrapleural effusion.

In this group no toxic reactions were observed. The dose was moderate and the course short. Since we were concerned about the possible effect of the drug in preventing sleep, we gave a hypnotic at night as a routine in our early cases. This was found to be unnecessary, however, with a daily dosage of 10 mg. of amphetamine, as used in this series. In all cases there was, besides the euphoria, a considerable improvement in appetite, and pains, headaches, and minor complaints disappeared. The beneficial effects observed by us in this series suggest that amphetamine might have a much wider application in general surgery.

ENCOURAGEMENT OF OVER-ANXIOUS PATIENTS

CASE 6.—An intelligent and "highly strung" professional man, aged 53, lived in constant dread that he might need collapse therapy; and, when it became necessary to carry out phrenic-nerve crush, a general anæsthetic was needed. The pneumoperitoneum which followed produced a nervous wreck, though a reasonable control of the diseased area in the lung was obtained.

We would have abandoned the pneumoperitoneum immediately had it not been that the result of amphetamine (given as "vitamin tablets") produced a fundamental change in his reactions. He improved both mentally and physically. His spirits became buoyant and his outlook optimistic. His appetite improved and he put on weight. He continued weekly refills without demur up to the time of discharge. Amphetamine was given for two weeks in all.

CASE 7.—An ex-Service man, aged 35, had had dyspepsia four years before admission. This had been associated with the prospect of going overseas, and no somatic cause had been found. While overseas he developed palpitations and cardiac symptoms, which were described as "functional."

On subsequently developing tuberculosis he was sent into this hospital with a recommendation for thoracoplasty. He complained of severe pain centred over the area of disease (he had been informed of its situation) and dyspepsia. No cause for these symptoms could be found.

The onset of hæmoptysis in a nearby patient was the signal for an additional symptom. The patient said he could taste blood in his mouth and must be swallowing the results of his hæmoptysis. This again proved unfounded, and, after attempting to convince him of the truth, we recommended some "vitamins" as a general tonic. Amphetamine, given as in the previous cases, rid the patient of his fears, and he has since been transferred to the surgical block, where he awaits thoracoplasty with equanimity.

---

[2] Bett, W. R. *Post-grad. med. J.* 1946, 22, 205.

of fibrinolysis before, and to a lesser extent after, operation. In order to test the obvious conclusion that premedication induces fibrinolysis, it was applied to 8 subjects (volunteers and coöperative patients) without other disturbing factors. One volunteer showed signs of toxæmia with vomiting, and developed well-marked fibrinolysis; the other subjects remained negative.

A possible factor to be considered is the *fear* of an impending operation felt in varying degree by most patients. It is difficult to assess the extent of this agitation, since some patients are anxious to conceal it, but in at least 14% of patients before operation it seemed to be the only likely factor responsible for fibrinolytic activation. This conclusion, though of considerable inherent interest, reduces the value of the further investigations described (with extreme brevity therefore) below. It is now uncertain whether the results obtained were related to the mental or to the physical state of the patients.

C. *Accidental Trauma.*—Blood samples from 12 cases of accident were obtained before treatment, and a clinical estimate of the degree of shock recorded. Fibrinolysis occurred in 4 cases—2 of head injury with moderate shock, 1 of Pott's fracture with moderate shock, and 1 of a cut wrist with negligible shock. Two patients with severe multiple injuries and extreme shock showed no fibrinolysis.

D. *Miscellaneous Pathological States.*—No attempt was made to carry out a comprehensive survey, but, to gain preliminary information as to the incidence of fibrinolysis in disease, blood samples were examined from 90 patients undergoing routine pathological investigation. Of these, 11 showed fibrinolysis, and in the following conditions the figures in parentheses indicate the number of patients positive or negative in each category:

> Ulcerative colitis (2+, 3−); rheumatic carditis (1+, 1−); serum sickness (1+, 1−); nephritis (1+, 1−); cold agglutination associated with Raynaud's phenomenon (1+, 1−); toxæmia of pregnancy (1+, 5−); cirrhosis of liver (1+); lead poisoning (1+); urticaria (1+, 2−); iritis (1+).

All other cases were negative, including transfusion reactions, drug reactions, sepsis, tuberculous and other infections, peptic ulcers, rheumatoid arthritis, metabolic disorders, anæmias, and malignancy.

DISCUSSION

From the foregoing observations, no single factor or process emerges with any clarity as the activator of fibrinolysis.

The surgical and accident cases provide results showing that traumatic shock is not the major agent. This is borne out by the observations of Macfarlane (1937) and Imperati (1937), in which quite minor procedures were associated with relatively intense fibrinolytic activity. These previous investigations did not include the immediate preoperative period, a study of which in the present work has revealed the importance of preoperative disturbances as causes of fibrinolysis. One of these disturbances appears to be premedication. It has been shown that fibrinolysis was induced in a normal subject by morphine and atropine, though the particular subject seemed to be unduly sensitive to them. A similar sensitivity may partially explain the greater incidence of fibrinolysis observed in patients who received premedication as compared with those who did not, but in 7 experimental subjects no activation by morphine and atropine was observed. It would be unwise to attach much significance to the small number of positive results obtained in a miscellaneous group of pathological states, but the nature of the latter might suggest a condition of hypersensitivity as a possible common factor, though it must be remembered that in other cases of hypersensitivity negative results were obtained.

In the absence of any other obvious explanation it is reasonable to suppose that anxiety or fear may have been related to a proportion of the preoperative positive results. This supposition is supported by the observations of Latner (1946), who found fibrinolysis in a few normal persons during air-raids on London. If it is correct, the origin of fibrinolytic activity must be sought in the physiological responses to mental as well as to physical disturbances. This view, taken in conjunction with the other findings in the present and previous work, suggests that spontaneous activation of the proteolytic system of normal blood may be a part of the "alarm reaction" as defined by Selye (1946).

SUMMARY AND CONCLUSION

Fibrinolysis occurs not only after surgical operations but immediately before them in about 50% of cases.

The drugs used for premedication may be responsible for some cases of preoperative fibrinolytic activity.

Fear of impending operation appears to cause a further proportion of positive results.

Traumatic shock does not seem to be a major factor in determining fibrinolysis.

The activation of the proteolytic system of normal blood, almost certainly responsible for the phenomenon of fibrinolysis, may be a part of the "alarm reaction" of Selye.

Thanks are due to the surgeons and anæsthetists of the Radcliffe Infirmary whose ready coöperation has made investigation of these cases possible; to Miss E. M. C. Dyke for help in collecting samples; and to Mr. J. Pilling for undertaking much of the work in the laboratory. The general investigation of fibrinolysis is financed by the Medical Research Council.

AMPHETAMINE IN PULMONARY TUBERCULOSIS

L. E. Houghton
M.D. Camb.

Fintan L. Corrigan
L.R.C.P.I.

From the County Hospital, Harefield, Middlesex

Contrary to popular belief, euphoria or spes phthisica is not often encountered during the active phases of pulmonary tuberculosis. The prevailing mood is commonly one of depression and over-anxiety.[1] The influence of personality is recognised by most clinicians as an important factor not only in the ætiology of many cases of phthisis but also in the prognosis of cases under treatment. Apprehensive, over-anxious, and introspective patients seldom do well. These factors are perhaps particularly important in view of modern developments in treatment which involve major surgical intervention, the patient very often associating successful treatment with major surgery. The patient who enters a modern sanatorium can no longer contemplate a period of tranquillity and freedom from personal anxiety, but must face a series of collapse-therapy measures beginning perhaps with phrenic-nerve interruption or artificial pneumothorax or pneumoperitoneum, and advancing, in the case of failure of these measures, towards the irreversible procedure of thoracoplasty. The effect of this protracted ordeal on apprehensive personalities is often ing blood and glucose-saline, was 9 pints; the estimated output, allowing for blood-loss, oozing from wounds, gastric suction, sweating, and respiration, was $4^1/_2$ pints leaving an excess fluid intake over output of $4^1/_2$ pints. During the second twenty-four hours the estimated excess fluid intake over output was 2 pints, the third twenty-four hours $1^3/_4$ pints, and the last twenty-four hours 1 pint.

---

[1] Some of the words and phrases used in this paper have a special meaning in psychiatric medicine. We have not used them in this sense.

Autopsy (nine hours after death).—There were no signs of jaundice. The subcutaneous tissues were œdematous and the blood rather watery. The lungs showed extensive œdema, a common terminal event in acute uræmias of this type, where intravenous fluids are administered after the kidneys have almost ceased to function. None of the tissues showed any sign of dehydration. The wounds in the stomach and jejunum were healing well, fluid passed readily along these viscera, which were not unduly distended, the colostomy was patent, and there appeared to be no obvious reason why the abdominal injuries should not have resolved completely.

The kidneys were swollen, their combined weight being 14 oz. (normal is $10^1/_2$ oz.). They showed no evidence of trauma. On section, the renal cortex was pale and swollen, with prominent glomeruli; the centres of the pyramids were pale, but the corticomedullary junction was clearly demarcated. The renal pelves showed small splashes of submucosal hæmorrhage. The bladder held about 1 oz. of reddish urine containing blood-pigments and albumin.

Microscopically the kidneys showed the characteristic changes of an acute nephrosis, such as is found in post-transfusion deaths, the principal features being bloodlessness of the glomerular capillaries, with swelling and increased cellularity of the tufts, and a tendency to clubbing; widening and increased tortuosity of the convoluted tubules, with flattening of the degenerated lining epithelium; reddish or brown finely or coarsely granular material in the tubules of Henle's loops; and a similar substance in the collecting tubules mixed with desquamated degenerated epithelial cells. The pigmented appearance of the casts was preserved in unstained sections.

Blood Examination.—In this case there was no real reason to believe that sulphadiazine was the cause of the uræmia. At no time were crystals of the drug found in the urine, and the case was predominantly one of hæmoglobinuria and not hæmaturia. From the time the first specimen of urine was examined we had reason to suspect the transfusion, and during life the following tests on the blood of the patient and the first three donors were carried out. (As the hæmoglobinuria preceded the last transfusion, the fourth donor is not considered here.)

(1) Blood-group of patient: group A_1, Rh positive.

(2) Patient's *own cells* mixed with his *own serum*: no hæmolysis or agglutination (*a*) at room temperature, (*b*) in refrigerator.

(3) Test *group-O cells* mixed with *patient's serum*: no hæmolysis or agglutination (*a*) at room temperature, (*b*) in refrigerator.

(4) Cross-matching with the three donors, group O: no agglutination between any of the three *donors' cells* and the *patient's serum*. During *reverse* cross-matching agglutination naturally developed between the patient's cells and the sera of the three donors, but in the case of the second donor this was very pronounced.

(5) *Agglutination-titre of the three donors' sera against the cells of three stock group-A and three stock group-B bloods.*

(i) α 1/256 β—1/128
(ii) α 1/4096 β—1/1024
(iii) α 1/512 β—1/128

(6) In view of the very high titre of α agglutinins in the serum of the second donor, this serum was mixed in a watch-glass with group-A blood in proportions approximating to the actual transfusion. Gross agglutination rapidly developed. The red-cell counts of the test blood before and after addition of the serum were 4,900,000/c.mm. and 2,450,000/c.mm.—i.e., allowing for slight dilution of the blood by the serum, nearly half of the red cells had been destroyed in the process. Controls with normal serum showed a drop of only 8% in the red-cell count, to be explained by the dilution.

DISCUSSION

The theoretical dangers of transfusing patients of other groups with universal donor blood containing high-titre agglutinins have long been recognised (Levine and Mabee 1923, Freeman and Whitehouse 1926, DeGowin 1937); and Gesse (1935) collected 46 post-transfusion accidents of this type (20 of which were fatal) from the literature, along with a case of his own where the group-O serum of the donor agglutinated the corpuscles of a group-A recipient in a dilution of 1 in 2048. Muller and Balgairies (1936) reported a case of shock following a transfusion of group-O blood with high α agglutinin titre to a group-A recipient. Riddell (1939) and Wiener (1943) both advise against giving group-O blood to patients of other groups when the agglutinin titre of the donor is high, but they do not specify at what titre the blood should be rejected.

Earlier papers show some difference of opinion, probably depending on the technique of titring, about what is the normal α agglutinin titre in group-O blood. More recently Aubert et al. (1942) examined 250 unselected group-O sera and found that in over 70% the titre ranged from 128 to 512, although exceptional titres of 8192, 16,384, and even higher were recorded. At no. 1 Base Transfusion Unit, M.E.F., where 1000 universal donors' bloods were titred, the average range was 64–256 (Buttle).

Aubert et al. (1942) describe an experiment in which they gave 450 c.cm. of group-O blood, with an α agglutinin titre of 16,384, to an anæmic patient: this was followed by mild intravascular hæmolysis but not by hæmoglobinuria. Similar experiments led them to conclude that "the transfusion of conscious recipients of group A (12 cases) with considerable volumes of group-O serum or plasma containing extremely potent anti-A iso-agglutinins did not produce any reaction which could be classed as dangerous." All showed some evidence of red-cell destruction in the recipient, however, with the symptoms, in some cases, of pain in the back, constricting sensations in the neck and chest, and intestinal colic and nausea; but the suggestion is made that these might be due to unidentified substances in the serum. However, they recommend that group-O blood with an α agglutinin titre of 512 upwards should be considered undesirable for transfusion purposes.

Various methods of demonstrating the "dangerous universal donor" have been described (Weil 1915, Rous and Turner 1915, and Coca 1918). The best of these appears to be that of Coca, somewhat modified by Levine and Mabee (1923). This test consists of mixing the donor's citrated blood, diluted 1 in 10 in normal saline, with the recipient's whole citrated blood. Dilution and mixing are performed in a white-cell counting pipette, and the reaction is observed on a glass microscope slide. A reaction is read as negative if no agglutination appears at the end of fifteen minutes. It is also possible to determine whether the recipient's or the donor's cells are agglutinated. In the former case nine-tenths of the cells are clumped, while one-tenth of them are free; in the latter case the reverse is found.

The absence of any post-transfusion reaction in our case is not necessarily significant. Wiener (1943) points out that, when the patient is under an anæsthetic, the symptoms may be unnoticed; and that, even when the patient is conscious, the first symptoms may be those of uræmia.

The histological appearances of the kidneys are not peculiar to transfusion deaths and have been described in fatal cases of blackwater fever, crush uræmia, sulphapyridine poisoning, and other conditions. A study of 30 kidneys from one or other of these conditions has led us to believe that the pigmented casts are the debris of degenerate desquamated tubular epithelium and not broken-down red cells, although the discoloration appears to be due to a hæmatogenous pigment. Often these casts affect less than 20% of the collecting tubules, and it is probable that degenerative change in the convoluted tubules, though less conspicuous histologically than the pigment casts, is a more important factor than mechanical blockage. This view conflicts with that of Baker and Dodds (1925) but is in agreement with recent papers by DeGowin et al. (1938) and Bywaters and Dible (1942).

CASE 8.—A trained nurse, aged 28, with disease in the right lower lobe associated with atelectasis, had been "difficult," uncoöperative, and emotionally unstable during her treatment in this and other hospitals. Her disease, in these circumstances, made little progress towards resolution, and collapse therapy was unhelpful. She became increasingly introspective and listless and finally became morbidly religious and prepared herself for her end. She made arrangements to return to her home in Ireland.

A course of amphetamine sulphate produced considerable but not dramatic improvement in her state of mind and in her physical well-being. Her temperature settled and she asked to get up. Previously she had feared to get out of bed in case she should have a hæmoptysis. She undertook bed occupational therapy for the first time.

Her passage to Ireland having been arranged, this patient could not be followed up. It was interesting that, as a trained nurse, she knew what treatment she was having, and anticipated and complained of sleeplessness. This was overcome with hypnotics.

CASE 9.—A woman, aged 31, had been diagnosed as tuberculous a few months after a confinement. On admission to this hospital she had fairly extensive bilateral tuberculosis. She complained of headaches and of bizarre symptoms, such as "burnings and tinglings in the head" and "rushing of water through the ears." She was depressed at being admitted to a sanatorium and did not think she would be able to continue treatment.

A course of amphetamine sulphate, given as before, produced some increase in nervous symptoms, and she complained of sleeplessness. The drug was therefore discontinued.

During the next three months the symptoms continued, and no organic cause could be found. A second course of amphetamine was started, and this time improvement was striking. She lost her symptoms, became cheerful and coöperative, and is at present running a football pool in the ward.

In this series the drug was given not to assist the patient over a particularly trying situation but to lessen the strain of a long stay in hospital and perhaps to reverse some of the tendencies which seem to be inherent in tuberculosis.

DISCUSSION

In a disease such as phthisis, where the interplay of psychosomatic factors has such an important bearing on the development and progress of pulmonary lesions and on rehabilitation, a safe drug which reinforces confidence obviously has a wide field. An objection to the use of a drug of the ephedrine group might have been its tendency to raise blood-pressure and produce tachycardia. But these are not among the physiological effects of amphetamine in moderate dosage. Again, interference with sleep might have been disadvantageous in a condition where rest is of paramount importance. In the first place, however, amphetamine, as used by us in small doses and administered in the morning, does not produce insomnia. On the contrary, by allaying fears and anxieties, it has tended to have the reverse effect. Hypnotics have only occasionally been necessary in our series. Moreover, amphetamine is not a physical stimulant, and its effect in promoting increased physical effort seems to be psychological. Probably amphetamine should be withheld from excitable patients. We have found it desirable not to tell the patient what drug he is having.

From the limited number of patients treated in this way it is impossible to draw conclusions or to define clearly the type of patient or the circumstances in which amphetamine should be used, but in our preliminary series the impression has been formed that it is valuable and apparently harmless.

SUMMARY

An account is given of the effects of amphetamine sulphate (benzedrine) on patients undergoing institutional treatment for pulmonary tuberculosis.

The drug appears to have a definite value, particularly during difficult phases of thoracic surgery and for the restoration of confidence in the depressed or over-anxious patient.

FATAL USE OF A DANGEROUS UNIVERSAL DONOR

A. D. MORGAN
M.B. Aberd.

GEORGE LUMB
M.D. Lond.

John Burford Carlill Laboratories, Westminster Hospital Medical School

THE following case illustrates a rare type of inco patibility in transfusing a group-A patient with blo from a group-O donor, where the high-titre seru agglutinins of the latter caused agglutination of t recipient's corpuscles, followed by hæmoglobinur uræmia, and death. Such incompatibility is not reveal by the standard cross-matching tests (donor's ce against recipient's serum) and was only brought to lig by subsequent titring of the donor's serum.

CASE-RECORD

A healthy soldier, aged 38, was wounded by a revolv bullet, which entered the body $1^{1}/_{2}$ in. below the right cost margin and made its exit through the left flank. The patie was admitted to a military hospital half an hour later, ful conscious. He vomited some dark blood, and at the same tin gas escaped from the entry wound. Pulse-rate on admissic 84. Blood-pressure 130/76 mm. Hg. He was catheteris before operation, and clear urine was obtained.

Operation.—Three-quarters of an hour after admission tl abdomen was explored through a left paramedian incisio 'Pentothal,' nitrous oxide, oxygen, and ether being us during anæsthesia. The bullet had passed obliquely throug the stomach, from left to right, producing two large woun of the lesser curvature, very ragged, and separated by a narro strip of gastric wall. This strip was divided, and the whol wound sutured in two layers. A second wound of the jejunum involving three-quarters of its circumference, was likewis sutured. A large wound of the transverse colon was expose the affected loop of bowel clamped off, and the afferent an efferent limbs gun-barrelled by a running suture, the clamp being left in situ.

During the operation one pint of glucose-saline was adminis tered intravenously, followed by two pints of blood. Afte operation a third pint of blood was given. All three dono were group O, the blood being cross-matched by the usu slide technique, with no suggestion of incompatibility. Durin the transfusions the patient was anæsthetised, and no untowar reactions were observed.

Progress.—Next day the patient was conscious but still i a critical condition, with a pulse-rate of 140 per minut Since admission he had had a total of 18 g. of sulphadiazin On the third day gastric suction and intravenous salines we continued, but the sulphadiazine was stopped. As the patie had not passed urine since the operation he was catheterise and 6 oz. of dark brown turbid urine was withdrawn.

Laboratory Reports.—Hæmoglobin 85%. Urine aci pH 5·3; albumin +++; urobilin +; benzidine reactio +++; deposit of much amorphous material, with *only* a occasional red cell; sulphonamides present but *no* crystals i deposit. Conclusion: slight hæmaturia, gross hæmoglobinuri

By the fourth day the general condition was unchange Pulse-rate 120–140. Only 6 oz. of urine was withdrawn b catheter, still containing large amounts of albumin an hæmoglobin. A further pint of blood was given, with glucos saline containing 100 c.cm. of 4·3% sodium sulphate to th pint. During the taking of blood for estimation of urea th surgeon noticed that the red cells appeared to settle abnormall quickly. *Laboratory report:* blood-urea 223 mg. per 100 c.cm

On the fifth day a purpuric rash appeared, the patient wa mentally confused, and his general condition had deteriorate The total urinary output for the day was $3^{1}/_{2}$ oz. withdraw by catheter. *Laboratory report:* urine clearer in colour strongly alkaline; albumin +++; benzidine reactio +++; sulphonamides present, but no crystals in deposit.

Later in the day he was cystoscoped, and both renal pelve were washed out with normal saline. The colostomy wa active, the pulse-volume good, the pulse-rate 100–120; bu during the last three days only 17 oz. of urine had bee obtained, by catheter or cystoscope. The patient becam more and more deeply unconscious and died the same night 100 hours after his injury.

Fluid Balance.—The fluid intake and output were estimate daily. The intake during the first twenty-four hours, includ-

10 mm. constitute a negative reaction. A control test with saline should be done. As Naterman and Robins (1942) point out, these skin tests do not accurately reflect drug sensitivity, but at least serve as a rough index. In the ocular test both eyes are first inspected, and then one drop of 35% diodone is placed in one eye, the other eye acting as a control. The patient is instructed to close his eyes, and they are then observed at $1\frac{1}{2}$ and 3 min. A positive reaction consists of injection of the conjunctival and scleral vessels.

As a final safeguard, before the full injection of diodone, 2 c.cm. is given intravenously, and the patient is observed for untoward effects over the next 2 or 3 min. Adrenaline solution 1 in 1000 is kept at hand ready loaded in a syringe.

If there is no significant reaction to these tests, the patient is given morphine gr. $\frac{1}{4}$ and transferred to the X-ray department. A blood-pressure cuff is put in place just above the knee of the more affected leg. Under 2% procaine local anæsthesia the saphenous vein is then exposed at its termination as in the Trendelenburg operation. A main tributary of the saphenous vein is isolated and the needle introduced into it. The patency of the infusion system and the resistance to injection are then tested by injecting a little warm saline. This is followed by the final test dose of 2 c.cm. of 70% diodone. Before the rest of the diodone is injected, the pressure in the sphygmomanometer cuff is raised above the venous pressure in the limb, so that during the injection there shall be less dilution of the diodone with venous blood from the leg. To this precaution we attribute in part the fact that the veins show up with adequate contrast in the radiograms, though the rate of injection is considerably slower than that usually recommended in angiographic work. With a 50 c.cm. Luer-Lok syringe containing about 30 c.cm. of 70% diodone and an 18 B.W.G. needle, 20 c.cm. is injected in as many seconds. This rate is approximately maximal under these conditions, for not only are the bores of the needle and vein small but also there may be the additional resistance of an extensive bed of tortuous collateral vessels. Radiographic exposures are made at 5, 15, 25, and 35 sec. after making the injection, which is maintained at the rate of 1 c.cm. per sec. The optimal shadow is likely to be obtained in the films taken after 10–20 sec. As long as 3 sec. is taken for each exposure at 78 kilovolts and 60 milliamps with an anode height of 42 in. The films are taken with a Potter-Bucky diaphragm.

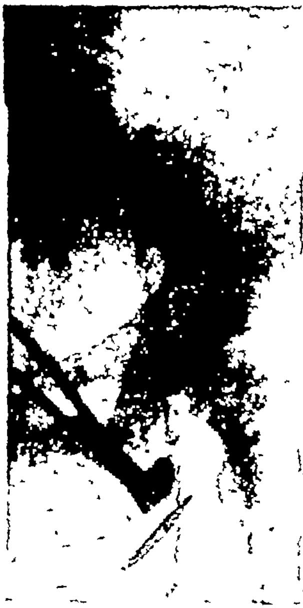
Since no more than a tributary of the saphenous vein is used for the injection, the main saphenous trunk is not sacrificed, only the tributary being doubly ligated before the needle is withdrawn. There have been no untoward complications from the procedure, and it has not been thought necessary to keep the patient in hospital for longer than one night. Contra-indications to this method of phlebography are the presence of severe renal or hepatic disease and sensitivity of the patient to diodone.

CASE-RECORDS

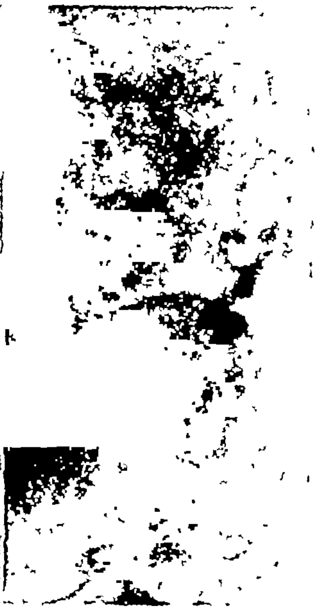
CASE 1.—A tailor, aged 43, had had attacks of numbness and cramp in the left leg for two years. During that time a fine network of superficial veins appeared on both thighs. There had been no œdema, nor had the varicosities extended on to the abdomen.

On examination he was well developed and rather obese, with no abnormal signs except the prominent veins already noted. These veins were not more than 1–2 mm. wide, and no larger veins were visible, even after the application of a tourniquet. The arteries in the lower limbs were normally palpable, but the left leg was colder than the right. There was no œdema.

In view of the fact that the symptoms, which might have been of vascular origin, appeared at the same time as the abnormal visible veins, it was thought worth while to investigate the venous return from the left lower limb by phlebography. Only 35% diodone was available at the time, but 30 c.cm. of this injected into the left saphenous vein was sufficient to demonstrate that the external and common iliac veins were patent as far as the inferior vena cava, with no visible collaterals (fig. 1).



1



2

Fig. 1—Diodone solution (35%) was injected into a tributary of the left saphenous vein and can be seen coursing up external and common iliac veins. No collateral vessels visible.

Fig. 2—Diodone concentrated solution (70%) was injected into the left saphenous vein. None of the diodone can be seen in the iliac veins or inferior vena cava. There is a large tortuous collateral, probably the inferior epigastric vein. The opacities in the region of the ilium represent injections of bismuth.

CASE 2.—A Belgian woman, aged 54, had had attacks of pain in the upper abdomen since childhood, recurrent jaundice for seven years, periodic enlargement of the abdomen for four and a half years, and varicose veins on the legs and trunk for three and a half years. She had contracted syphilis thirty-five years previously, and her blood Wassermann reaction was still positive.

The varicosities had appeared first in the right leg and later in the left leg, and had spread up both legs, appearing at the same time in the groins and sides of the abdomen and lower chest, both anteriorly and posteriorly. The only symptom attributable to the distended veins was a burning pain in the left leg, and this was the immediate reason for her last admission to hospital.

On examination she was a rather plump vivacious woman apparently in fair health. Temperature, pulse-rate, and blood-pressure were normal, and, apart from the varicosities, the only signs of disease related to the liver. The liver-edge was palpable 2 in. below the right costal margin in the mid-clavicular line and felt firm and irregular. The spleen was doubtfully palpable, and there were no signs of free fluid in the abdomen. The palms of the hands were flushed, and a few spider telangiectases were seen. Liver-function tests showed only minimal impairment. The blood-flow in the varices was chiefly towards the heart, though the venous valves were partly incompetent. There was no caput medusæ, and the only site of œdema was the left ankle, where it was slight and of the chronic brawny type.

Syphilitic cirrhosis of the liver was diagnosed. The question then to be settled was whether the abdominal varices were secondary to the cirrhosis and possible portal obstruction, or whether, besides the cirrhosis, there was an independent obstruction of the inferior vena cava. The distribution of the abdominal varices, mainly along the flanks and at the groins, favoured the intrinsically less likely double diagnosis. This question was definitely settled by the phlebogram (fig. 2). The injected diodone was absent not only from the inferior vena cava but also from the external iliac vein on the side used for injection. The main channel for the venous return was a large tortuous vessel, probably the inferior epigastric vein.

It is of interest that the varicosities first appeared in the right leg in case 2, because in the development

It is fortunate that transfusion accidents of this type are very rare, in view of the difficulty of preventing them. In our case the α *agglutinin titre* of the second donor was 4096, an extremely high figure; and dilution by the recipient's serum did not prevent agglutination of the recipient's own corpuscles. Yet, by the ordinary cross-matching technique (donor's cells against recipient's serum) the blood appeared to be compatible; and, as the α agglutinins of any group-O donor will cause *agglutination of group-A cells on a slide*, the reverse cross-matching test (donor's serum against recipient's cells) is nearly always omitted. Indeed, the only way in which such incompatibilities can be anticipated is by the method of titring the donor's serum in every case. However, where large numbers of universal donors are employed in blood banks, it appears desirable to accept only those with *agglutinin titres below a certain arbitrary level.* The titre of 256 for α seems to be the upper limit of safety.

SUMMARY

A patient with group-A blood died after transfusion with group-O blood containing exceptionally high α agglutinins.

The clinical, post-mortem, histological, and serological findings are described.

The value of titring donors' sera is discussed in relation to the rarity of such accidents.

Our thanks are due to Colonel G. H. Haines for permission to publish the case, and to Miss S. Hartoch for technical assistance.

THROMBOSIS OF THE INFERIOR VENA CAVA

TECHNIQUE FOR ITS DEMONSTRATION

J. M. STOWERS

FIRST ASSISTANT, X-RAY DIAGNOSTIC DEPARTMENT

UNIVERSITY COLLEGE HOSPITAL, LONDON

THROMBOSIS of the inferior vena cava is usually regarded as an incidental happening, often difficult to diagnose with certainty and, in any case, of little more than academic interest. Recent investigations, however, reveal not only that it is commoner than is realised but also that it may *be of practical* importance and call for intervention.

Pleasants (1911), in a review of 314 cases, has classified its causes in the order of frequency: neoplasms; puerperal sepsis; typhoid, tuberculosis, and scarlet fever; disease of liver; trauma; localised infections; and congenital obstruction. He concluded that the obstruction was usually recent when detected, and most often took place *in the* distal inferior vena cava and spread up from the iliac veins.

The type of case which is most susceptible to treatment, and therefore most important to diagnose, is a *spreading* thrombophlebitis or a phlebothrombosis, the latter being, according to DeBakey et al. (1943), a form of thrombosis which develops without much, if any, associated inflammation to fix the thrombus. In such cases ligation of the inferior vena cava is claime to save life by combating pulmonary embolism an sudden extension of the thrombus to both renal vein (Whittenberger and Huggins 1940).

The first reported therapeutic ligation was done b Trendelenburg in 1911 in a case of puerperal sepsis wit thrombosis (Pfaff 1926). After the operation there was dramatic improvement in the septic condition.

Krotoski (1937), who collected 48 such cases, conclude that ligation of the inferior vena cava and ovarian veins we the treatment of choice for pelvic thrombophlebitis.

Collins et al. (1943) reported on 8 cases so treated and had one death in a patient already moribund before operation They consider that ligation of the *inferior vena cava lowers* th mortality as compared with other operative procedures, and *that delay in operation or over-conservatism is dangerous.*

Gaston and Folsom (1945) reported 2 more successful cases both of whom had had *pulmonary emboli from the lower limbs*

The principle of proximal ligation in the treatmen of venous thrombosis in the limbs is gaining ever mor authoritative support (Ochsner and DeBakey 1941 and b) and seems to apply with equal force to cases wit venous thrombosis in the pelvis, so long as th *appropriate* ligation *is not too severe an operation.*

Ligation of the inferior vena cava does not produc more than slight disability, and this only in a few cases.

Wakefield and Mayo (1934) reviewed 19 cases of ligatio of the inferior vena cava; 15 patients survived the operation 2 of the deaths being regarded as due to the operation the *ligature* cutting through the vein on the twenty-thir day after operation in one case, and in the other case the ligature being tied above the right renal vein. This was therefore not *an instance of simple ligation. Of the survivin* patients 5 had persistent œdema of the lower extremities, 3 *had transitory* œdema, and 6 had no œdema. The observation that none developed visible collateral circulation was significant, though it is not known in what proportion of cases, if any, the inferior vena cava was recanalised.

Burch and Winsor (1943) reported *an interesting* post-operative physiological *study of patients* after ligation of the inferior vena cava: the elimination of water from the body was unaffected; the venous pressure in the legs was increased after the operation but *tended to approach normal* after time; and, though persistent postoperative œdema might be *present, erythema, petechiæ, pallor, paræsthesiæ, hyper*æsthesia, and tenderness were absent, and arterial pulsation *were much diminished.*

Northway and Greenway (1944) have suggested tha the unpleasant sequelæ *in the lower limbs* after thrombosi of the inferior vena cava can be reduced by combinin ligation with lumbar sympathectomy. This suggestio is based on the view of Homans (1941), Leriche an Geisendorf (1939), and Ochsner and DeBakey (1939 1940, 1941a and b) that in femoro-iliac thrombosi trophic changes in the legs are due to vasospasm, whic can be abolished by sympathectomy.

Hitherto investigation has been hampered by th difficulty of diagnosing *cases in the acute stage,* whe alone treatment might be of use. *It* therefore seem worth while to record a reliable *method of* diagnosin thrombosis of the inferior vena cava and its immediat tributaries at any stage of its development.

TECHNIQUE

The method consists of injecting a solution *of diodone,** a radio-opaque substance, into the saphenous vein nea its junction with the femoral vein, *and making* radiograms during and immediately *after the injection.*

Sensitivity to diodone should always be tested eithe by the intradermal method (Naterman and Robins 1942 or the ocular method (Robins 1942). *In* the intraderma method 0·05 c.cm. of 35% diodone *is injected* into th skin of the flexor aspect of the forearm. *This* normally produces a weal 2–4 mm. in *diameter.* A weal measuring less than 8 mm. and an erythematous area of less than

Vitamin Therapy—its uses and limitations

PREGNANCY

WITHOUT COMPLICATIONS

An increasing number of mass experiments such as that of the People's League of Health in London, which involved observations on over 5,000 women, and the Toronto Survey, which was on a rather smaller scale, have demonstrated beyond question the desirability of supplementing antenatal diet with the essential protective factors. The practice of the war years in this respect has contributed to the drop in the maternal mortality rate (including abortions) from 3.10 in 1939 to 1.92 in 1944 and to a decline in the sepsis rate which is described in the report of the Chief Medical Officer of Health as "remarkable."*

For such supplementation of pregnancy diets, the best preparation is the one whose formula is based upon the gap between average normal diets and optimal requirements.

PREGNAVITE

A single supplement for safer pregnancy

The recommended daily dose provides :

vitamin A	4,000	i.u.	vitamin E ..	1.0 mg.	iodine	not less than 10 parts per million
vitamin D ..	300	i.u.	nicotinamide	25.0 mg.	manganese	
vitamin B_1	0.60	mg.	calcium ..	160.0 mg.	copper	
vitamin C ..	20.0	mg.	iron ..	68.0 mg.

Product of Vitamins Limited

UPPER MALL, LONDON, W

of the inferior vena cava it is the right longitudinal dorsal venous channels which become incorporated into the renal and postrenal segments of the inferior vena cava and are therefore not available as collaterals if this vessel is obstructed (Keen 1941).

SUMMARY

A technique is described for demonstrating the patency of the inferior vena cava.

The possible practical importance of such a demonstration is indicated.

We are indebted to Mr. P. Brand and Mr. R. H. Shephard for supervising the operative procedures, and to Mr. J. M. Kenny for his assistance in the radiographic work.

Medical Societies

SOCIETY OF MEDICAL OFFICERS OF HEALTH

IN his presidential address to the fever group in London on Nov. 8. Dr. WILLIAM GUNN spoke on the use in the last twenty years of

Human Blood Derivatives for Transfer Immunity

With gains in knowledge of plasma and serum, he said, difficulties tended to increase rather than diminish. The loss of serum's protective potency with age, appreciable in less than a year even when stored at 4° C and largely due apparently to the presence of denaturing enzymes, had been countered by freeze-drying in vacuo, whereby further loss was probably averted. Since preservatives tended to interfere with the drying process, various substances had been tried, and phenol, originally selected as the one of choice, was still used because it has the best all-round antiseptic action; the time taken in drying was only slightly prolonged, provided that the ratio of the total volume to the surface area was kept low. A 5% solution was used, to make a final concentration in the serum of 0·5%; the only disadvantage was that in higher concentrations than this phenol caused coagulation of the proteins. After the solution was added, 5 ml. of the contents of the ampoule (always to be preferred to a rubber-capped bottle) corresponded to only 4·5 ml. of actual serum—a point almost invariably overlooked by clinicians in the estimation of dosage.

In some 20,000 administrations no proved case of homologous serum jaundice had been encountered; but the long incubation period and the difficulties of follow-up in a large area such as London must be remembered. In recent years donors had been supervised for 4–5 months after withdrawal of blood, but sub- or non-icteric hepatitis remained a possibility which even repeated blood-counts and van den Bergh tests might fail to bring to light. There was still no conclusive evidence that antiseptics, or drying, or even heating to 57° C for four hours, as had been done on specially stabilised gamma-globulin, was effective in neutralising the causative agent in homologous serum jaundice; probably the complicated physico-chemical processes which take place in the separation of plasma-proteins into their constituent fractions alone sufficed.

Experience had shown that the adjustment of dosage, strictly by age or weight (*such as* 0·1 ml. per lb. body-weight for gamma-globulin), was not entirely satisfactory; at ages below 1 year and above 3 years the prophylactic dose against measles tended to be flattened compar with that in the relatively susceptible 1–3 years grou at least in London and other large centres of populatio Furthermore, it was not easy to administer the exa dose, especially in fractions of a millilitre, to a struggli child; if protection was imperative, the average do must be exceeded.

Rubella serum had been collected for preventio among women in the early months of pregnancy, bu the appropriate dose had not yet been fixed; it probabl lay between 10 and 20 ml., depending on the interv between the date of exposure and time of injection Preliminary trials had shown the protective titre to b rather lower than that usually found in measles serum possibly because the infection stimulus was less intens The gamma-globulin fraction would naturally be muc more effective—approximately 25 times more poten as had been shown in trials of mumps convalescent seru by Gellis, McGuinness, and Peters in 1945.

Reviews of Books

Aids to the Diagnosis and Treatment of Venere Diseases

T. E. OSMOND, M.B. Camb., honorary consultant venereal diseases to the Army. London: Baillièr Pp. 138. 5s.

THIS is a new volume in the "Students' Aids" serie Venereal diseases were formerly dealt with as a sectio of dermatology, but the subject has enlarged so muc and—as the author says in his preface—has so little i common with diseases of the skin, that it has bee decided to separate the two subjects. Dr. Osmon writes clearly and well, and gives a comprehensive out line of modern teaching in the short space at his disposal Inevitably the matter is condensed, but there are fe gaps. There are some omissions, such as reference t the skin rashes which may complicate sulphonamid therapy, and to the important evidence that post arsphenamine jaundice may result from faulty sterilisa tion of syringes and needles. Some of the author views will not be generally accepted. He states, fo instance, that healthy seminal vesicles cannot be felt b the examining finger, and implies that rectal stricture may result from gonococcal proctitis. For those wh require to revise under pressure, or those in practic who need a handy and accessible guide to first principle this book should prove very useful.

Motor Disorders in Nervous Diseases

ERNST HERZ, M.D., instructor in neurology, College Physicians and Surgeons, Columbia University, Ne York; TRACY J. PUTNAM, M.D., professor of neurolog and neurological surgery at the college. London Oxford University Press. Pp. 184. 20s.

Dr. Herz and Professor Putnam have made te teaching films of the disorders of movement which ma be found with lesions of the nervous system. This litt book has been compiled to supplement the cinemat graphic demonstration, and there is no doubt that t whole constitutes a contribution to the teaching neurology. The book is freely illustrated from the fil and from standard anatomical works; but without t dynamic presentation of the films it loses nearly all t authors have to offer. Patients with parkinsonis hemiplegia, facial palsy, or ophthalmoplegias can readily be seen and examined that strips of cinemat graph film can hardly offer anything new to the studen and it is so easy to show a student how to elicit a tend jerk that pictures of it appear unnecessary. The seco half of the book, dealing with motor disorders of t cranial nerves, is more interesting, but even here t knowledge gained is fragmentary, for the sensory fun tions of the nerves are omitted. The book by itself h little to offer for those with access to patients; the boo and the films together will help to drive home clinical lesson

---

A Primer for Diabetic Patients, by Prof. Russell M. Wild (Philadelphia and London: W. B. Saunders. Pp 192. 9s. has usefully gone into a sixth edition to meet the nee of the vast numbers of diabetics who are treated an guided to health at the Mayo Clinic. Diet, insulin test and the way of life are clearly explained.

THE LANCET
LONDON: SATURDAY, DEC. 14, 1946

Origins of Child Care

Our child-health services have a wide territory to cover—antenatal care and midwifery, infant consultations, nursery schools, health visiting, the school medical service, care of the child in sickness, his protection from neglect and exploitation, care of the unwanted child, and youth organisations. Prof. Richard Ellis, in his recent inaugural lecture in the department of child life and health in the University of Edinburgh, reviewed the beginnings of these services against the background of the ndustrial revolution. It is instructive but saddening to see how often an advance in the care of children has followed a shock either to the public conscience or to more sensitive private consciences. Captain Thomas Coram, ashamed to see the numbers of dead babies thrown on dunghills, got a royal charter for the establishment of the Foundling Hospital; Lord Shaftesbury and Dr. Barnardo worked tirelessly for the protection of destitute and exploited children; Dr. William Farr, under the auspices of the Obstetrical Society of London, showed that between half and three-quarters of the confinements in the country in 1869 were in the hands of untrained midwives; the trials of Margaret Waters and of Mrs. Dyer revealed that the mortality of infants entrusted to baby farmers was between 60 and 90%; the low physical standards of the young men recruited for the Boer War stimulated the development of the school medical service; the O'Neil case provoked the Curtis report. It is therefore comprehensible that the child-health services today "are not," as Professor Ellis said, "a neatly designed and constructed pyramid with a Minister perched like Athena's owl on the summit," but are more like a vast rambling country house.

> "By far the oldest structure is the block now labelled Central Administration. Antiquarians have discovered traces of Saxon workmanship in the foundations devoted to local government, while the Norman oubliette is still in constant use for the disposal of troublesome memoranda. An orphan presenting himself at the door may find himself the responsibility of any one of seven ministries or of more than seventy voluntary organisations. While the Lords of the Admiralty, the War Office, the Royal Air Force, and the Ministry of Pensions usually know which babies it is their privilege to hold, the Ministry of Health, the Ministry of Labour, and the Home Office appear to be in some doubt."

He believes that no future child-health programme can be efficient until the whole system of divided and ill-defined responsibility has been overhauled.

The greatest influence for good on the health of the older child, Professor Ellis holds, has been not a health service or doctor, but the late Lord Baden-Powell, who "had the vision to see that there was a place for a non-military, non-political youth organisation," designed to encourage an open-air life, independence and initiative, service to the community, and the fundamentals of good citizenship. His scheme makes these principles attractive to boys, and canalises their natural interests during the "gang age." The growth of the scout and guide movements, with their membership of five million, is evidence of Baden-Powell's grasp of the needs of youth. Several advances in the care of children have been the outcome of wars: the evacuation of Basque children during the Spanish war taught us lessons which were valuable when British children were sent to reception areas; and the verminous condition of many of those children gave a new impetus to the child-care services. The pædiatrician, in fact, must interest himself in more than the care of the sick child. Child health, Professor Ellis pointed out, is closely related to social and economic conditions—which may depend on international policies and upheavals—and to education in citizenship; and the pædiatrician, like an Eastern deity, must have hands to spare for the obstetrician, the general physician, the parent, the educationist, the child psychologist, the youth leader, the juvenile employment bureaucrat, and all workers in preventive and social medicine. Nor should he be afraid to help in shaping the social policy of the community in which he works. He is one of a team approaching the same goal: that the sick child should be healed, the destitute child cared for, and every child have the chance of a happy healthy childhood with training in citizenship.

Bacterial Motility

The student of elementary bacteriology traditionally wastes an hour or two of his practical class-work in attempting to stain the flagella sported by motile micro-organisms, and he can rarely have hesitated when asked the function of these appendages. Yet now Pijper,[1] who has for many years been observing bacteria under dark-ground illumination, makes the claim, well supported by argument and illustration, that, so far from being the organs of locomotion, the flagella are the result of this process. By special methods of cultivation it is possible to grow organisms which are motile but lack flagella. In Pijper's view the single or multiple "tails" seen by staining or other means are composed of the slimy substance that surrounds many bacteria, especially when young, and appears, in the pneumococcus for example, as a capsule. It is the motion of the organism that causes the capsular substance to trail out behind, like the tattered gown of a scholar rounding the corner of Balliol on a March morning. The faster the motion the longer is the tail. How then do motile bacteria progress? Direct observation is difficult owing to the speed of movement. Pijper overcame this obstacle by suspending the organisms in methylcellulose, an inert substance sufficiently viscous to slow down the movement so that it could be observed directly and by cinematograph. He found that motile organisms progress by spinning on their long axes while their bodies are bent in a slight spiral curve—much as does the rubber "sand-eel" used by pollack fishermen. The classical shape of the cholera vibrio is, in fact, an exaggerated example of that of all motile bacteria.

If these views are accepted some long-standing questions relating to bacterial motility are solved.

PROLONGED CONTACT *antiseptic*

During a systematic investigation into the antibacterial activity of the monoaminoacridines, 5-aminoacridine emerged as an antiseptic having properties similar to those of proflavine 'Flavogel' (5-aminoacridine) is the Glaxo preparation of this potent antiseptic in a water-miscible jelly base for use on cuts, wounds and protective dressings, etc. 'Flavogel' is valuable also as an antiseptic lubricant for catheters, cystoscopes, and specula, and in ante-natal examinations. 'Flavogel' has a powerful antibacterial activity, is effective in the presence of serum and is prolonged in action. The consistency of the jelly base maintains the antiseptic in contact with the tissues enabling it to exert the maximum antibacterial effect 'Flavogel' is ready for application direct from the tube. It is convenient to carry, clean to use and does not stain skin or clothing.

'Acramine' (5-Aminoacridine) is available also as a powder for making up solutions.

FLAVOGEL

Manufacturers of Penicillin

5-Aminoacridine Hydrochloride in water soluble jelly base 1-oz. tubes and 9-oz Jars.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX BYRon 3434

B.D.H. CONTRAST MEDIA

for use in X-ray Diagnosis

IODATOL—Iodised Oil B.P.
For the usual purposes for which iodised oil is generally employed, *e.g.*, bronchography, hysterosalpingography, localisation of cord tumours etc.

SHADO-CREAM and **SHADOFORM**—Preparations of Barium Sulphate B.P.
For oral or rectal administration in X-ray visualisation of the gastro-intestinal tract.

PHENIODOL B.D.H.
For oral administration as Pheniodol Meal B.D.H. in cholecystography.

T.I.P.—Iodophthalein B.P.
For those radiologists who wish to continue to practise the older method of cholecystography T.I.P. is still available in forms suitable for intravenous and for oral administration.

IODOXYL B.D.H.—Iodoxyl B.P.
For intravenous pyelography and arteriography.

X-Ray/E/24

should be considered potentially though not necessarily dangerous in a child. In adults daily doses up to 25 mg. (1,000,000 I.U.) have been given, sometimes with ill effects and sometimes without. Some adults get toxic symptoms and reversible renal impairment after taking 5 mg. a day for several months, while others on the same dosage escape. **Dowling** and **Prosser Thomas**[5] think that there will be no great risk of serious sequelæ with the maximal dosage they employ in lupus—150,000 I.U., or 3·75 mg., daily—though anorexia and depression were noted in a fifth of their patients. It seems best to make it a rule, as **Freeman** and his colleagues[6] suggest, that in patients receiving large doses of vitamin D for more than a few days a careful watch should be kept for a rise in serum-calcium or incipient failure of renal function, which should be the signals for immediate reduction n dosage. Moreover, it must be borne in mind that n calciferol treatment there is an initial exacerbation f local disease, which may be dangerous. It should e widely known that the most concentrated vitamin-D reparations are not suitable for self-medication, and ven under medical supervision should not be dministered in large dosage for trivial ailments.

Annotations

RELAPSING BENIGN TERTIAN MALARIA

Critical appraisement of new drugs for the treatment of malaria is by no means the simple matter it might at first appear. At least a decade and a half elapsed before the merits and the limitations of mepacrine were properly appreciated, and it was only under the stimulus of war in the tropics that real progress was made. This stimulus led to intensive search for new antimalarial drugs, among which 'Paludrine' takes a high place. Although it is generally agreed that in most respects paludrine is superior to any of the drugs previously in common use, this drug is not the complete therapeutic answer to the malaria problem. Its outstanding merits are the remarkable range of doses effectively arresting clinical attacks of benign tertian (B.T.) and malignant tertian fever, and its freedom from toxicity or undesirable side-effects.[1] That it will prevent or eradicate a *Plasmodium falciparum* infection has been amply demonstrated,[2] but its ability to sterilise the more chronic and resistant *P. vivax* infections is still unproved. A report by Dr R. D. C. Johnstone in our last issue records comparative studies of treatment with 50 mg. and with 500 mg. of paludrine daily for ten days, and with combined quinine and pamaquin for a similar period. From these studies it appears that a combination of quinine and pamaquin is more effective in preventing relapse within six months than is either dosage of paludrine. Nevertheless, although the quinine-pamaquin treatment seems to be twice as effective as paludrine in preventing relapses, the relapse-rates after it were by no means insignificant. That the relapse-rate after an acute attack is twice as high with one form of treatment as it is with another is an important observation, but it is only one part of the picture. Against this achievement must be set the facts that quinine in the dosage advocated has unpleasant side-effects, and that the use of pamaquin necessitates the patient's retention in hospital, if not in bed, during its administration.

It has been amply demonstrated that suppressive treatment with small doses (100 mg.) of paludrine twice weekly prevents clinical relapse of B.T. malaria, and that this treatment can be given for long periods without inconvenience or danger.[2] The relapses which may follow paludrine treatment can thus safely and surely be prevented by subsequent administration of this drug in remarkably economical dosage. Relapses following quinine-pamaquin treatment, on the other hand, cannot be suppressed by a continuation of these particular drugs in any dosage which is free from side-effects, and, in the case of pamaquin, free from the danger of grave toxicity.

It is impossible to forecast which cases of B.T. malaria will relapse after either paludrine or quinine-pamaquin treatment of an attack: it is certain that some will do so sooner or later in the absence of further treatment. In these circumstances it may prove that paludrine can be given more profitably in therapeutic dosage for a day or two only, to arrest the attack, and then in 100-mg. doses at biweekly or weekly intervals over a period of, say, six months. This would involve little alteration in the gross amount of drug consumed, and would ensure that every patient could continue his normal life and vocation throughout this period without interruption by relapsing malaria. A study of the relapse-rate after such a procedure would be interesting. The problem of relapsing B.T. malaria is of immediate importance, and it still awaits satisfactory solution.

PART-TIME NURSES

> "Towards the end of 1945 the position of the county infirmaries in Gloucestershire in regard to the supply of nursing staff became desperate. In some hospitals the matron was the only qualified nurse on duty for long periods, and it seemed inevitable that some, if not all, of the infirmaries would have to close down."

In his foreword to a memorandum[1] from the Gloucestershire County Council, Dr. T. B. H. Haslett is describing a state of things to be found at present, in greater or less degree, throughout the country. The difference lies in the fact that Gloucestershire has solved the problem. Dr. Haslett outlines the transformation in the infirmaries which followed the introduction of a competently planned and well-run part-time nursing service. Mr. W. A. Shee, the public-assistance officer to whom the credit for the scheme must go, first appealed for part-time nurses in February of this year. By a bold and imaginative stroke it was decided that they should be asked not merely to supplement the full-time staff but to *become* the staff, augmented where possible by any full-timers available. This completely new departure could only be managed by rearranging the nursing work in all the county infirmaries: and, thanks to the collaboration of the matrons, this was done. The interests of the existing full-time staff were safeguarded, and the influx of newcomers made it possible to shorten and redistribute their hours of work.

The appeal was for four kinds of recruit—trained nurses, enrolled assistant nurses, nursing attendants, and nursing orderlies—and so could be made to all women in the area. All suitable candidates who came forward and offered to do a few hours' duty were welcomed, and those engaged soon acquired a loyalty to the infirmaries in which they served. Many, when asked, were willing to arrange their home lives in such a way as to do a regular four-hourly shift, and all who were thus regularly employed got privileges which encouraged their steady attendance. A brochure setting out their terms of service has been distributed, and it is written with singular freedom from small tyrannies. The writer clearly does not think in such phrases as: "They have got to understand that . . .", "They will have to . . .", "We can't have them. . . ." The attitude is rather: "What transport, what meals, what uniform do women who take on this work need and deserve?"

The working day has been divided into four shifts: 8 A.M.–12 NOON, 12 NOON–4 P.M., 4–8 P.M., 8 P.M.–8 A.M. No

For example, the early bacteriologists gave very varied accounts of the number and position of the flagella of any one species: if the flagella are no more than trailing tags of capsular substance this disagreement is not surprising considering the diversity of methods used to demonstrate them. Such has been the difficulty in deciding by direct observation whether an organism is motile that modern practice has turned to the functional test of the Craigie tube or "motility agar" in which the bacterial growth is seen to spread. One argument of PIJPER's is not quite convincing. He remarks that many motile bacteria, described in the textbooks as "rods," are often seen in stained preparations to be curved; but the same may be said of *Mycobacterium tuberculosis* or *Corynebacterium diphtheriæ*. Where too lies the essential difference in cell structure between *Salmonella typhosum* and *Shigella sonnei* by which the first can flex its body, spin, and move, while the second remains in rigid immobility stirred only by the molecular buffeting of brownian movement?

It is probably too near to teleological heresy to ask what advantage motility confers on an organism. Can *Bacterium coli*, like Leander, stem the ureteric stream and reach his Hero in the kidney?

Dangers of Calciferol

IN the last ten years, with the introduction of concentrated preparations of vitamin D in convenient forms, very large doses have been administered not only in rickets but also in a variety of intractable conditions including arthritis, hay-fever, psoriasis, the common cold, and lately lupus and other forms of tuberculosis. The startling success reported in lupus may well lead to a wider (and wilder) use of these preparations without due regard to their known dangers Soon after the antirachitic action of irradiated ergosterol was discovered toxic effects of overdosage were reported in animals, and during 1928–31 many cases of toxicity in man were recorded in Germany.[1] These were due to a particular brand of irradiated ergosterol called 'Vigantol,' a German preparation containing a high proportion of toxisterol, which is more toxic than calciferol and has less antirachitic activity. It is not surprising that doses of vigantol as low as 2·5–5 mg. had toxic effects Unfortunately, however, toxisterol was not the sole cause of the trouble, for in 1932, when pure crystalline calciferol was obtainable, toxic effects in animals and later in man were described once more, though a higher dosage was needed to elicit them.

The toxic effects of calciferol (vitamin D_2) are identical in animals and man,[2] and appear to be simply an exaggeration of its physiological action. The symptoms of overdosage in children have recently been described by DEBRÉ and his colleagues[3] These French observers have had personal experience of 9 cases, and have collected published data concerning others, including 10 deaths Anorexia is the first invariable symptom, and it appears suddenly and may become total in two or three days Nausea, with vomiting in the more severe cases, appears a little later, equally suddenly. The child complains of diffuse aches and pains, particularly in the head and epiga trium, and he becomes apathetic, pale, drowsy, torpi and later cachectic, confused, and stuporose; the is polyuria and polydipsia, with impaired ren function and disordered calcium and phosphor metabolism. Constipation is usual, sometimes aft an initial diarrhœa, and the child gets up at night t urinate and to drink, as kidney function deteriorate The picture will often suggest tuberculous meningiti but the cerebrospinal fluid is normal, and the tempera ture is not raised except in severe cases. Signs o central nervous system involvement, such as apraxi aphasia, convulsions, and cerebral vascular accidents have been noted in the terminal stages of fatal case Hypertension is a common finding but not an earl one; it may not develop until a few days after th drug has been stopped and may persist for severa weeks, even worsening for a time, although no mor calciferol is given. The urine may contain albumi and calcium phosphate crystals. Kidney-functio tests show an impaired ability to concentrate the urin and impaired clearance of phenolsulphonphthalein The blood chemistry is all-important in the diagnosis Blood-calcium is almost (but not quite) invariabl raised, and there is a high level of blood-phosphoru and blood-urea. Radiography may reveal calcificatio in soft tissues and lungs and rarefaction of bones The prognosis is excellent if the diagnosis is made in good time and the calciferol discontinued As a rule kidney function and blood-pressure return to normal and there are apparently no lasting ill effects.

The pathology is reasonably well known from the small number of necropsies and from animal experiments. At first the excess of calciferol causes an unusually large proportion of the dietary calcium to be absorbed in the gut. Calcium and phosphorus contents fall in the fæces and rise in the urine The more calcium there is in the diet the easier it is to produce signs of intoxication—hence most authorities agree that the calcium intake should be kept low during massive vitamin-D therapy. Later, when the animal stops feeding, the high blood-calcium level is maintained at the expense of the bones, and osteoporosis results. There is a negative balance of both calcium and phosphorus, and a fall in the blood and kidney phosphatase. Calcium is deposited, following its high concentration in the blood, in renal tubules, bronchi, the walls of large blood-vessels, heart, stomach, and soft tissues. In young animals excessive deposition in the epiphyses takes place, interrupting growth, an effect which has not yet been reported in children. This metastatic calcification apparently occurs where phosphatase is most abundant. All these effects are identical with those caused by an overdose of parathyroid.

The most important question in practice—how much calciferol will cause these symptoms—cannot be precisely answered, because there is a wide individual variation in the toxic threshold DEBRÉ's children had ingested a total of 60–150 mg "over a short time", he thinks that a considerable number of subclinical and undiagnosed cases occur, and that mild toxic symptoms might result from a single dose of 15 mg of pure calciferol in a child. According to PARKS,[4] a daily dose of over 1 mg. (i.e., 40,000 I.U.)

group of organisms presents many difficulties, and it may well be that they often escape recognition. Dr. G. M. Findlay, at the same meeting, suggested that it might be useful to find out whether streptococci isolated from rheumatic joints are ever contaminated with members of the group; he also thinks that the effects of inoculating streptococci into joints already infected with pleuropneumonia-like organisms should be studied. Two uncommon human diseases in which the group may be implicated are Haverhill fever (generally held to be caused by *Streptobacillus moniliformis*) and Reiter's disease; both conditions are characterised by polyarthritis, and Findlay suggests that all cases should be thoroughly investigated for pleuropneumonia-like organisms. It must, however, be remembered, as Salaman and others[1] have pointed out, that these organisms are fairly commonly parasitic in man, so their isolation from patients with a particular disease is not enough. Even if investigation fails to show any connexion between the pleuropneumonia group and human rheumatic infection, these organisms can be used to set up an infective arthritis in rodents and thereby provide us with a new, if oblique, approach to a difficult problem.

THE MIND IN PHTHISIS

As Dr. George Day pointed out on Nov. 16, resistance to tuberculosis remains a mystery because it does not follow the usual rules. The bacillus often attacks young people whose resistance to other diseases is presumably high; and many of them do not seem to have been subjected to recognised predisposing conditions such as malnutrition, overcrowding, bad working conditions, and exposure. As the share of the mind in the body's ills becomes increasingly clear, it is natural to look closely at the mental accompaniments of diseases which have always been accepted as purely somatic. This Dr. Day has done, with results that whet curiosity. Certainly the prospect of a long illness is not always unwelcome: the young person who finds adult responsibilities heavy, and love denied, may in fact look forward to six months' enforced idleness in friendly surroundings as a respite. Whether this state of mind would encourage his tissues to give the tubercle bacillus "a good home instead of destroying it or imprisoning it for life" is a question which needs studying from many aspects. It is conceivable that anxiety—which can influence the secretion of glands, raise the blood-pressure, and injure the gastric mucosa—can also alter the body chemistry in a way favourable to the tubercle bacillus. Certainly the disease attacks many at an age when the emotional demands of sex are at their height; and an undue proportion of these young patients, Dr. Day considers (though he gives no figures), have recently had an unhappy love affair. He gives an example in which anxiety deriving from this source seemed to hinder the healing process; and other factors, such as escapism and guilt, seem to have been accompaniments in his subsequent cases. The converse of the picture is the rapid and unforeseen recovery of a young woman whom an exacting family life seemed to suit better than the classical remedy of rest. It would be useful to know whether other tuberculosis workers share his experience that some 30% of a sanatorium population are sick in mind as well as body.

It must be remembered, of course, that the patient with tuberculosis has good grounds for anxiety in his disease, quite apart from other troubles; indeed, Dr. Houghton and Dr. Corrigan, whose paper we print this week, find that anxiety and depression colour the prevailing mood more often than spes phthisica. Moreover, instead of the long peaceful illness to which, perhaps, he has been unconsciously looking forward, the modern tuberculous patient must face collapse therapy ranging from artificial pneumothorax to thoracoplasty. Fear of operations, however slight, is both deep and common, and for an apprehensive patient treatment may itself become a severe emotional strain. Houghton and Corrigan, discarding the customary sedatives, have made bold and successful use of amphetamine ('Benzedrine') in some of these cases, counting on its ability to stimulate the nervous system. Their results will no doubt encourage others to make further trials on the same lines.

BRADFORD WANTS A MEDICAL SCHOOL

Colonel M. Stoddart-Scott, M.D., M.P., has presented a memorandum to the Minister of Health stating that a medical school, which would train 50 undergraduates a year, could be set up in Bradford in time to accept its first students next October. The memorandum is the outcome of the deliberations of a conference of representatives of the city health department, the local medical profession, the hospitals, and the Bradford Technical College.

The college, which has applied for recognition as a university college, is already recognised by London University for the first M.B., and its facilities could be expanded to include full preclinical training. Clinical work would be undertaken at the Royal Infirmary and at St. Luke's, a pioneer municipal hospital of high standing. The school would be prepared to train students for the M.B. examinations of London and Leeds as well as for the English and Scottish Conjoint examinations.

Admittedly Bradford is near to Leeds, but its own population is close on 300,000, and with its immediate environs the population of the district exceeds a million. Thus it is at present the largest centre of population *without a university*. A more potent argument against the new proposals may be the suggestion of the hospital surveyors of the Yorkshire area that Leeds should confine itself to undergraduate teaching and Bradford become the postgraduate centre of the region.[1] The reaction of the General Medical Council, the Minister of Health, and the Lord President of the Council to the memorandum will be awaited with interest, not only in Bradford but in all the other areas where plans for new medical schools have been mooted, so far without success. This proposal, and others like it, will also raise problems connected with the size and shape of the projected hospital regions.

TRADE-UNION MEMBERSHIP

WE commented last week on the action of certain local authorities in requiring their staff to join a trade union. As reported in our Parliamentary columns, the Minister of Health has now reminded local authorities that "their primary duty as health authorities is to maintain the efficiency and smooth running of their health services and to ensure the welfare of the patients for whom they are responsible." All other considerations, he points out, must be regarded as secondary. "While the Minister is anxious that doctors, nurses, and members of similar professions should join a trade union or appropriate professional association, he considers that this matter should not be determined by the unilateral action of local authorities."

Last Monday the Willesden council decided to suspend all action on its recent resolutions about conditions of employment.

THE Order of the Garter has been conferred on Viscount ADDISON, F.R.C.S. He is the first doctor to receive this honour.

The *American Practitioner*, which began publication in September, is a monthly journal (50s. a year post free from J. B. Lippincott Co., Aldine House, Bedford Street, London, W.C.2) intended for articles "not of a highly specialised nature in the fields of general medicine and surgery."

---

[1] Salaman, M. H. and collaborators *J. Path. Bact.* 1946, 58, 31.

[1] See *Lancet*, 1945, ii, 681.

part-time nurse need undertake night duty unless she wishes. Those who do 24–28 hours weekly on day shifts, or three nights a week, are regarded as regularly employed. “Reserves” are on the waiting-list for regular duty. Those who do less than 24 hours' day work a week, or less than three nights, are regarded as casual workers.

On day duty trained nurses get 2*s*. 6*d*. an hour, enrolled assistant nurses 2*s*., nursing attendants 1*s*. 9*d*., and nursing orderlies 1*s*. 6*d*. On night duty the rates are £1 5*s*. nightly for a trained nurse, £1 for an enrolled assistant nurse, 17*s*. 6*d*. for a nursing attendant, and 15*s*. for a nursing orderly. Any nurses doing more than 28 hours' day duty, or more than three nights weekly, are paid proportionately on the Rushcliffe scale.

These rates, when compared with the present cost of domestic help, cannot be called high; yet they have attracted women to part-time service, which shows that objections to work in hospitals are not primarily financial.

Transport in public-hire motor-cars is provided from approved centres, and travelling time is allowed as an extra. In cases where part-time nurses have to make a considerable journey by bus or train they may be allowed fares. Time is allowed for meals on duty, and night staff have a break of two hours besides the time allowed for meals. All meals are served in the nurses' quarters, not on the wards, and are substantial. The morning and evening shifts, for example, are given a meal of fried sausages, or scrambled eggs, or beans on toast, with tea, coffee, or cocoa; the afternoon shift and those on night duty get a two-course dinner and a cup of tea. Night staff coming from a distance may also be given breakfast on coming off duty. Every part-time worker gets 2 or 3 dresses of the appropriate colour for her rank, and 3 caps and 6 aprons; these are all of modern type, and are laundered without charge.

Regularly employed part-time nurses are given four weeks' leave with pay after the first year's service. They are also allowed sick-pay at reasonable rates.

Some 150 part-time nurses are now working in the nine county infirmaries, and more are wanted, though some infirmaries already have a waiting-list of nursing staff. At no time have any of the infirmaries or their wards been closed for lack of staff; and at one infirmary a new wing of 12 beds for operable cases of malignant disease has been opened, and is staffed almost entirely by part-time nurses.

The scheme has not proved unduly expensive, despite the provision of transport. Sums formerly spent on engaging nurses from coöperatives have been saved, and the authority has not had to provide quarters and personal laundry for part-time workers. The patients are well satisfied: Dr. Haslett describes them as “full of praise for the attention they receive.” For one thing, night staff having been reduced to a minimum, all morning bed-making and washing is left to the day staff, and patients are allowed to sleep undisturbed till 7 A.M.; for another, many of the part-timers are older women who take a personal interest in their patients, and thanks to their short span of duty they come to work in a fresh and responsive spirit. The wards are no longer made tidy in time for the doctor's morning visit; and the doctors are glad of it. They see the nurses going on with their work while they make their rounds, and they can judge nursing standards better. The full-time nursing staff now do an 8-hour span of work, either from 8 A.M. to 4 P.M. or 12 NOON to 8 P.M. With the meals allowed on duty their hours have fallen considerably below 48 a week, and they fully approve the part-time system. It is worth emphasising this, because full-time nurses have sometimes objected to the introduction of a part-time scheme on the ground that part-timers get the choice of the pleasant shifts, while the permanent staff are obliged to take the unpopular shifts. Actually, the work of the full-time staff is so much lightened and so much better distributed that this objection has little force. It is also sometimes said that matrons dislike the system because it needs so much organising. This may be answered from Mr. Shee's experience that “there are no stronger advocates of the scheme in the county today than the matrons.”

Here surely is an answer to one of our most acute nursing problems, the care of the chronic sick. Local authorities with infirmaries to staff should write for the Gloucestershire memorandum.

GRANULOMATOUS LESIONS OF LIVER IN KALA-AZAR

THE atrophic and fibrotic lesions of the liver due to *Leishmania donovani* in visceral leishmaniasis in man have been described many times. So have the granulomatous lesions of the skin in post-kala-azar dermal leishmanioid, which appears as an occasional sequel to visceral leishmaniasis, usually a year or so after treatment, and has been thought to indicate a readjustment between man and his parasite.[1] But in visceral leishmaniasis of dogs, caused by *L. canis*, which despite its alias is almost certainly identical with *L. donovani*, granulomatous lesions of the liver and other viscera were described by Redaelli.[2] Now Bogliolo [3] reports the discovery of such hepatic lesions in visceral leishmaniasis in man; apart from the granulomatous foci, the rest of the liver presents the appearance which is characteristic of visceral leishmaniasis affecting that organ, there being no other signs of inflammation. He interprets the formation of these granulomatous lesions as a local reaction to the products of disintegration of dead parasites, independent of the atrophy and fibrosis initiated by the living parasites.

EXPERIMENTAL ARTHRITIS

THE study of rheumatic diseases in man has been hindered by the absence of spontaneous or easily induced arthropathies in animals. On the bacteriological side it is at least clear that various streptococci can produce arthritis when injected into the joints of rabbits and other animals; and rabbits sensitised by an intravenous injection of streptococci are more likely to develop arthritis after a joint infection than uninoculated controls. These and similar findings have led to speculation about the sequence of events in human rheumatic disease, but the comparison of experimental and human infections does not lead far. One of the more interesting types of arthritis which occurs naturally in pigs and sheep is caused by *Erysipelothrix rhusiopathiæ*. Swine erysipelas is not uncommon in this country and takes two forms: an acute septicæmia or “the diamonds,” and a chronic infection with endocarditis or arthritis as the main manifestation. At a meeting of the Heberden Society on Oct. 25, Dr. D. H. Collins recalled that he and Dr. William Goldie had shown that in young pigs the disease is contagious and may be conveyed as an arthritis and not as an acute exanthematous disease. With repeated intravenous injections of the organism they were able to produce arthritis in pigs, and examination of the inflammatory changes in the joints showed focal collections of lymphoid and plasma cells in the synovial villi and other changes similar to those found in human arthritis. Human infection with *E. rhusiopathiæ* is well known as causing erysipeloid, but this is rarely followed by arthritic changes; and there is no evidence that the organism is important in cases of human arthritis.

With the discovery that pleuropneumonia-like organisms can cause arthritis in wild and domestic animals, many investigators sought these bacteria in human infections, and in 1939 it was claimed that they had been recovered from cases of rheumatic fever. This claim was later withdrawn, and since then they have not been cultivated from either joint exudates or tissues of patients with rheumatoid arthritis or rheumatic fever; but

outh Walians. and the country is divided by a central lock of mountains through which no road or railway et runs.

The new region suits South Wales well, for Cardiff is good centre with good doctors and a competent school. ut North Wales for clinical matters cannot depend on ardiff. To begin with, a patient could only be moved here via Shrewsbury and Hereford after a journey of everal hours in ambulance or train. for the alternate est route is tedious and there are no through trains. imilarly North Wales naturally lies in the Liverpool onsulting area. A Cardiff specialist is never seen there ; s a matter of practical convenience consultants from iverpool. Manchester, or Birmingham are automatically alled in. Again most of the local doctors have been rained at the Liverpool school. which North Wales has ome to regard as largely her own. The proposal to set p a medical school at Bangor, which already has a niversity college, has encountered difficulties, for it es near the north-west corner of the area and has neither he staff nor the population to become a medical centre.

The local feeling is clear ; for at a recent meeting of anel practitioners it was unanimously resolved that orth Wales should be attached to Liverpool for clinical urposes. save for a few districts which are linked by ransport with Manchester or Birmingham. But a good ld British compromise may in the end evolve, for the inister has himself provided a loop-hole in saying that region may be allowed to have functions outside its wn area where desirable. It is thus possible that the octors will be persuaded to bow to the politicians, ntoning "Wales for the Welsh," provided that in ractice, at any rate for the present, they are allowed to tick to Liverpool and Manchester.

iverpool

The medical profession here are perturbed at the mall size of their region compared with that of their eighbour Manchester. Both cities have medical schools f about equal size, each admitting 100 undergraduates year. Yet Liverpool has been allotted a population of ust under $2\frac{1}{2}$ million while Manchester has nearly million. Furthermore the area assigned to Manchester $2\frac{1}{2}$ times as large as that of Liverpool. Students will end to apply for admission to the medical school which the centre of their area. Liverpool, drawing the same umber of students from a smaller area and population, ill, it is feared, ultimately have a lower standard of admision and a smaller chance of attracting outstanding candilates. Her school will thus be subordinate to Manchester.

So much for general criticisms. But the boundaries hemselves are held in several places to disturb the flow f students and patients to centres to which they are aturally linked by tradition, commerce, and transport. The most serious blow to Liverpool is of course the mputation of the North Wales area, which ignores xisting practice and planning alike. The hospital urveyors of the north-west area declared that Liverpool as the main centre for North Wales, and indeed also ished to associate Merioneth and Montgomery with it. ossibly in view of the inaccessibility of Cardiff the inister has it in mind to set up in North Wales a regional ommittee with delegated powers and its own office. ut if this regional committee were put under a regional oard at Cardiff. Liverpool would be left with esponsibility but without power or representation.

On the other hand it is felt that the Crewe area. includng Knutsford, which at present comes into the Liverpool egion, has obvious natural associations with Manchester.

To redress the balance between the Liverpool and anchester regions the following solution is put forward. orth Lancashire and South Westmorland (including arrow, Lancaster, Blackpool, and Preston) was desribed by the hospital surveyors as neutral territory etween Liverpool and Manchester, and though on the hole the surveyors recommended its assignment to anchester its transfer to Liverpool would not infringe ny medical principles. If this area and North Wales ere given to Liverpool, and the Crewe area moved to anchester, each region would then have a population f about $3\frac{1}{2}$ million and contain an approximately qual territory. Above all it would not leave Liverpool ith any feeling of grievance against its friendly neighbour anchester.

Manchester

There is a strong feeling here that the proposed areas in the north-west need revision. The basis of the trouble seems to be that North Wales, though generally dependent on Liverpool for its ultimate medical care, is placed under the ægis of Cardiff. In terms of travelling it would probably take three days for a patient or doctor to go from Colwyn Bay to Cardiff, have an interview. and return, whereas a similar visit to Liverpool could be managed in a day. The general opinion in Manchester is that, to make up for this district which it has lost, Liverpool has been given parts of Cheshire and Lancashire which have close associations with Manchester. The most striking anomaly is found in the case of Knutsford. Northwich, Lymm, and Congleton, all nearer Manchester than Liverpool and having no easy connexion with the latter city. Knutsford is in fact a residential suburb of Manchester, and Lymm largely so.

Several towns, including Wigan. Warrington, and Crewe, are almost equidistant from the two cities, and in point of distance and accessibility might be apportioned to either. But through their hospitals, and in some cases through their medical officers of health, these towns have asked that they should maintain their long-standing relations with the voluntary-hospital area of south-east Lancashire, represented by Manchester. A shift to the left would do much to satisfy both Liverpool and Manchester.

A small area in question is that of Saddleworth. This, though on the west side of the Pennines, is in Yorkshire : but its medical connexions are through Oldham and Ashton-under-Lyne on to Manchester. Its communication with the east is much less easy. It would be well allotted to Manchester.

Newcastle

The proposal to divide the country into regions is the least controversial part of the National Health Service Act. At first the regions will conform to the existing spheres of influence of the university medical centres, but as experience grows we must expect changes through the adjustment of border territories and the creation of new regions. There may be border troubles for some places. such as the clash between Cardiff and Liverpool over North Wales. Common sense and established practice would base North Wales on Liverpool, but Welsh nationalism will resist this. Over the remainder of the country the proposed regions will be accepted without much argument.

Drawing regional maps is the easiest part of the plan. What happens within the region matters. It is a momentous occasion, with an opportunity to provide the hospitals the country needs. But have we the men with the knowledge, experience, and imagination who will devote themselves to the work of the regional boards ? Have we the administrative officers who will be capable of entering into the life of the region and of wielding a proper influence ? The E.M.S. was good only in parts, and too many of its administrative officers had rôles which were innominate and obscure. From the outset the Ministry must strike a high note of promise and achievement. It will defeat its own purpose if it is too timid. Patience is a virtue only when it is used to a definite end. We have received the first intimations of the Ministry's plan, but we shall await their further proposals with some uncertainty. Is it too much to expect that the Ministry will capture the imaginations of the regional boards by describing some of the standards they expect them to attain ? Government buildings in the provinces and regional offices of the Ministry of Health do not give an impression of æsthetic charm or virile energy. Can the regional boards step off on the right foot and avoid the same impression ?

One of the boards' chief tasks will be to improve the hospital and specialist services in the big industrial districts. For this they will require the right man working in the right conditions and right environment. A period of work in a non-teaching hospital would be a great advantage. and might give a man opportunity to prove himself both in practice and research, thereby increasing the number of those eligible for return to responsible posts in the university medical centre.

Reconstruction

THE REGIONS

LOCAL COMMENTS ON MINISTER'S PROPOSALS

THE Minister of Health has proposed division of England and Wales into 14 regions, in each of which the hospital and specialist services will be in charge of a regional hospital board. Last week we published comments on the scheme as a whole. The following are comments from doctors working in the particular areas.

Bristol

From Bristol.—Many experienced administrators in the provinces are concerned that throughout the Minister's scheme too much stress has been laid on population and too little on distances and the natural grouping of areas —which in the south-west are very important. As regards population they maintain that the level has been set too high. Some feel that the "London view" has prevailed over "provincial experience." When areas and population are large, local views and interests are swamped and the service becomes "local government" in name only.

If all areas must be associated with a university medical centre, then Bristol is the natural headquarters of the south-western counties. But in this area distances are long—there are more than 250 miles from the northern end of Gloucestershire to Land's End. The Minister has foreseen some difficulties, and suggests a regional committee for Devon and Cornwall, responsible to the board "with delegated powers and its own offices." Everyone would agree that some division of the area is necessary. On the question whether or not there should be a committee responsible to the board for part of the area, opinions differ. It is not conducive to smooth administration to have a committee which cannot approach its university centre, or even the Ministry of Health, except through a regional board which is itself directly responsible for an adjacent area.

There is much to be said for two regional boards—each associated directly with Bristol as its university centre—even if the Minister rejects reconsideration of the case for having 30 or more regions for the whole country.

From Devon.—The hospital survey recommended a region extending from 25 miles east of Cheltenham to Land's End, based on Bristol. Consultants from Devon and Cornwall, meeting at Exeter in August, agreed that this region would better be divided into two.

The precise function of the university centre needs definition. In general, Devon and Cornwall have not looked in the past particularly to Bristol as their academic centre, and except in the last year or so, when resident posts for ex-Service medical officers have been arranged through Bristol, they have not regarded Bristol as a primary source of resident or consulting staff. Hence they would like to advertise their requirements throughout the kingdom and so have the widest possible field from which to draw applicants. An additional or alternative function for a university centre would be to supply experts in comparatively narrow specialties, such as neurosurgery and thoracic surgery. These would make tours of the region and either deal with cases in the area hospitals or move them to a university centre for investigation and treatment. A third function of the university would be to arrange postgraduate courses for practitioners. The consultants of Devon and Cornwall thought that the proposed region was too large and unwieldy to serve these two latter functions efficiently. Truro is about 170 miles from Bristol, and it was felt that such distances precluded satisfactory administrative contact. Finally, the population in the areas encircled by Exeter, Plymouth, and Truro is sufficient to justify the establishment of a separate regional organisation, and the appointment of specialists to cover all branches of medical and surgical work.

In Exeter there is already the nucleus of the university of the south-west, and there is a strong hope that ultimately a medical school will be started in association with it. Such a hope will be a stimulus to raise standard of medicine in Devon and Cornwall.

It is suggested that the regional boundary should approximately on a line joining Bridgwater and Bridp Such a line conforms to the existing natural catchm areas for the hospital and consultant services of Bri and Exeter. The region thus constituted would have its area centres Exeter, Plymouth, Truro, and possi Torquay. The choice of a regional centre lies betw Exeter and Plymouth. Those in favour of Exeter u the traditions associated with the county town, with existing university centre, and by including the Torq and Paignton group in their area they claim a populat not far short of Plymouth. Those who favour Plymou point to its more central geographical position, its lar population, and its greater hospital resources.

Wales

From the South.—The Government having refused appoint a Secretary of State for Wales, the Minister Health has offered a consolation prize by declari Wales and Monmouth one hospital region with university centre at Cardiff. In making this decision, he acceding to a request made to him unanimously by t local authorities of Wales and Monmouthshire, *and it* said that he was greatly impressed to find so mu unanimity in Wales on any subject whatsoever!

In the parliamentary debate (*Hansard*, July 2, 194 Mr. Bevan admitted that Cardiff is not easy of acce from North Wales, which pivots on Liverpool, but sa that nevertheless "there may be an administrati convenience in having one regional hospital board f Wales, with both Cardiff and Liverpool universiti represented on it." The case for administrative co venience has yet to be made out, and it is difficult t visualise any other convenience from the arrangemen proposed. From North Wales to Cardiff is a long an tiring day's journey, whereas from North Wales t Liverpool is a matter of an hour or so. So much fo the convenience of patients. As to the consultants c Cardiff (who incidentally are said to have joined wit the other consultants in Wales in voting unanimousl for Wales and Monmouth as a single area), these ar over-busy even at present in coping with the demands of Cardiff and its immediately surrounding areas. It i difficult to see how, even with air transport, they could possibly cater for the consultant needs of North and Mid-Wales. It is true that there are consultants also a Newport and Swansea, which are also situated in Sout Wales; but neither of these is a teaching centre lik Cardiff.

Possibly the Minister may have been influenced, in hi attempt to marry sentiment with practice, by consideratio of the record of the Welsh National Memorial Association which in 30 years has built up a comprehensive tuberculosis service which is claimed as being as complete efficient in the remotest parts of Wales as in the fou county boroughs. But a tuberculosis scheme has bee hitherto an ad-hoc scheme; and by the nature of thing easier to organise than a multi-purpose general medica and surgical service.

It is understood that the local *authorities, in* thei plea to the Minister to have Wales and Monmout declared a single area, suggested that, until the hospit and specialist services in the North and Mid-Wa areas are brought up to the necessary standard, th regional board shall be empowered to make arrangements with other regional boards, covering Liverpool, Manchester, Birmingham, and Shrewsbury. In another part of the speech already quoted, the Minister said: "we must have as much flexibility *as possible.* What is more, after the boards have *been set up* and we hav had experience, we must *have* modification. We shall certainly have to modify administratively."

The Welsh experiment *will be* well worth observation. It will be interesting *to see* whether Welsh national sentiment in action can produce sound practical achievements.

From the North.—Administratively and politically it is tempting, *especially* for a Minister from the south, to make Wales a region for the Welsh. But traditio and mountains *stand* in the way. The people of the north, with *memories of* Owen Glyndwr and Mortimer, hold themselves *(to* put it mildly) different from the

Lincolnshire. Fortunately, as the Minister has pointed out, the boundaries of regional areas need not, and will not, prevent the free passage of patients from one area o another; and there is no doubt that, as the regional boards become familiar with their regions, readjustments of boundaries will be made.

London, North-east

This region is to be based on the London Hospital and St. Bartholomew's, and is to include a sector of the metropolis combined with the larger portions of Essex and Hertfordshire. It therefore brings under one administration the Cockney and the extreme type of countryman, who may be only sixty miles apart in distance but whose outlook on life, including medicine, differs by hundreds of years. Essex villagers can still be found who regard London as "furrin parts."

The northward boundary does very much follow the present sphere of influence of London to the south and Cambridge to the north. Communication by road and rail to the larger centres has obviously been carefully considered and is satisfactory. If the large size of the region is going to do away completely with the hard demarcation line of the county boundary between Essex and Hertfordshire it will be a boon to those who have suffered so long from the jealousies and bickerings of the adjoining county councils. But where one boundary has been abolished, others will be created. And apprehension is naturally felt by doctors who live near the edges of the proposed new regions. The Minister will do well to allay their criticism at once, by reasserting his recent declaration that "the welfare of the patient must have priority over everything else," including administrative irregularities; and that doctors will not be penalised for sending patients over the boundaries of their region.

The other important point is the difference, already mentioned, between the rural and urban populations. The natural centres, such as Hertford, Bishop's Stortford, Chelmsford, and Colchester, must be allowed enough autonomy to be able to continue the good service they are already giving. The connexion with London must continue to help them, rather than to impose administrative restrictions.

It is of course difficult to consider the geographical problems of hospital regions when one knows so little about what they will imply; and it is impossible to give more than qualified approval until more is known about the workings of the regional administrations at different levels. With that reservation, local feeling in this part of the world is one of relief and satisfaction. We sincerely hope that further disclosures of plans will prove them to be as well thought out.

London, North-west

The regions centred on the University of London, having an average population exceeding 3 million, will present administrative problems never dealt with previously in this country. The sector scheme destroys administrative machinery already working, increases the size of the problem to be dealt with, and supplies no alternative to the machinery destroyed. Even were it possible for members of the regional board to be fully engaged in their duties, it is impossible to envisage their giving detailed consideration to the needs of an area stretching from Bayswater Road to Bridport. Does any super-specialist development within a hospital region demand a population of 3,843,250 (South-west) in order that it may be adequately organised?

The North-west region seems to have received an undue proportion of "cultural influence" by the inclusion within it of five undergraduate teaching hospitals and the main postgraduate teaching centre. This is the more remarkable when it is noted that its main population basis is the Middlesex County, wherein hospitals are not undeveloped. The separation of the North Middlesex and Chase Farm Hospitals from much of the population previously served will mean these two hospitals attempting to receive cases from areas separated from them by almost insurmountable geographical difficulties. This boundary, certainly, cannot be said to have been drawn for the benefit either of the patients or the local hospitals.

The planning, coördination, and provision of hospital and specialist services are stated to be the prime considerations determining the size and extent of the regions. If the regional hospital board is to fulfil these functions adequately it must ensure: (*a*) a bed bureau service, (*b*) allocation of function to individual hospitals, and (*c*) effective inter-hospital specialism. It should provide central legal, engineering, architectural, and purchasing departments, and all these should operate in close consultation with the individual hospitals. Considerable local autonomy should be encouraged amongst all hospital management committees. The efficiency of centralised supply and advice must be enhanced by constant contact with the periphery, where hospitals must enjoy purchase facilities of non-standardised equipment and dietary needs.

The danger implicit in the present suggestions is that efficiency will result in over-centralisation and be associated with an inaccessible bureaucracy. Without such centralisation it seems unlikely that the present non-existent regional machinery will fulfil its broad coördinating and supervisory functions.

We should, I think, limit the size of each region around London to approximately 2 million; attempt to base its administration on established organisations; and, where necessary, move the teaching hospitals as soon as possible into those outer regions where both the population and the hospitals have need of them. In the South-west region Southampton should become the autonomous centre, with its own university hospital within a few years.

London, South-west

The proposals have been well received here. As a base of academic learning and guidance, London University and its three medical schools, comprising a wide range of medical experience and administration, will, I believe, be more acceptable to the larger centres of population in the region than any alternative university centre. Three of the four larger county boroughs in the South-west London area—Portsmouth, Southampton, and Bournemouth—will also find it more convenient to link up with the metropolis for the inevitable consultations and meetings.

At first sight, the region, with a population of about 3,800,000, appears on the large side; but as Hampshire, Dorset, and the Isle of Wight are to have a regional committee, it is felt that more autonomy will be enjoyed by the group of hospitals within this sub-region. The larger area will also make it more economical to establish hospitals or units for highly specialised treatment—e.g., cerebral surgery, thoracic surgery, radiotherapy, and psychiatry.

The division of the local-authority responsibilities of Dorset and Wiltshire between two regions has apparent disadvantages, particularly as these authorities will have to provide services in both the South-west London and the Bristol regions, including epidemiological field work, and the visitation and follow-up of tuberculosis and venereal disease. However, the close proximity of these local-authority areas to the university centre of Bristol probably outweighs these disadvantages.

The grouping of hospitals and their ancillary services is long overdue, and one accepts the necessity of planning to provide more uniformity throughout the country. Even so, there are many links in the chain which appear to be missing, particularly the link between the hospital, specialist, and local-authority services. For example, in Southampton, where infectious cases arrive on ships, the port medical officer will no longer have any administrative control over the infectious-diseases hospitals which receive these cases. This may lead to difficulties over admissions for observation. It is to be hoped that, when the orders and regulations are considered, these matters, which are of great administrative importance, both locally and nationally, will successfully compete for clarification.

London, South-east

From Sussex.—The South-east region, based on Guy's and King's College Hospitals, includes only Kent and East Sussex and is about half the size of the South-west, which includes Dorset, Wilts, Hampshire, Surrey, and West Sussex. Moreover, the dividing line runs counter to the existing flow of medical services. It divides Sussex into two, an arrangement already shown to be incon-

Leeds

The area for the Leeds regional hospital board almost naturally defined itself. It has one central university, which is sufficiently far from other universities to make it an obviously independent unit; the surrounding population, though parts of it are concentrated into towns which merge almost imperceptibly into one another, is sufficiently separated from populous districts likely to belong to other regions that no difficulty could have arisen in their allocation to the Leeds region; and the population of the area is large enough to provide all the clinical material necessary for a numerous medical consulting staff, to provide enough of the rarer cases to make their advent a matter of intelligent interest rather than a unique occasion, and (most important of all in a university organisation) to provide a steady supply of pathological processes for scientific research and to satisfy all the teaching demands of a medical school.

The proposals defining the region, therefore, offer little ground for criticism. There is one district, however, which has been allotted to another region, which Leeds will probably desire to continue to draw to itself—Goole. Goole is mainly staffed by Leeds consultants and has been so for many years; the natural drainage is towards Leeds, and the reasons for allotting it to the Sheffield area are not very obvious. Northallerton, in the north, has been allotted to Newcastle, and some may feel that it should be part of the Leeds region, while on the other hand, in the south-west, Saddleworth remains with Leeds though its medical trend is towards Oldham and Manchester. Although for administrative tidiness it may be part of the Leeds region, patients will still go to Lancashire.

On a bird's-eye view the general provisions for the region are satisfactory to local interests, and the proposed arrangements coincide closely with the outline drawn by the Nuffield Provincial Hospitals Trust (Yorkshire region) and detailed in the report published by its medical services advisory committee, and also with the suggestion of the hospital surveyors.

Sheffield

My colleagues seem to be satisfied with the regional area, and no changes have been suggested.

Birmingham

Little criticism is heard here. The boundaries of our region seem to have been drawn in accordance with the facts of the situation.

Oxford

It had been feared that the area of the regional hospital board based on Oxford might correspond to Civil Defence Region 6, which included Hampshire and the Isle of Wight and had proved an inconvenient unit. Hence the immediate reaction here has been one of relief on finding that the proposed region corresponds fairly closely to the Berks, Bucks, and Oxon region of the Nuffield Provincial Hospitals Trust. The three counties have been working together closely and harmoniously in hospital affairs since 1940, and have jointly made many plans (some already realised) for coördination of specialist services. When a scheme for a cancer service was drawn up in 1944, Northamptonshire was associated with it, although not actually a member of the regional council.

The area now suggested has a population of about a million, with Oxford roughly at its centre. Though it is generally approved, a little boundary revision will be needed to ensure that natural catchment areas are not unnecessarily disturbed. We recognise that it is reasonable for the Maidenhead, Windsor, Eton, and Slough areas of Bucks and Berks to be included in North-west London, for all that there has been close collaboration of the local authorities and hospitals in this area with those of the rest of the Nuffield Provincial Hospitals Trust region. But we are less sure that this is true of the more westerly part of Bucks, embracing Amersham and the Wycombes; for, though the train connexions with Oxford are bad, and those with London are good, the road connexion with Oxford is excellent and there is a natural flow of patients from these areas to Oxford. On the north and north-east borders no special comment is needed; but on the north-west th is a strip of Gloucestershire, including Fairford a Moreton-in-Marsh, which from time immemorial h looked to Oxford for its specialist services and feels ve strongly that it should not be removed. On the sout west border there is the problem of Swindon and borough. Swindon has been a member of the Nuffie regional council; and, though from population size might be almost self-supporting for general speciali services, its plurality of hospitals conducted under vario bodies has made this difficult. It has been provided wi specialist services, as has Marlborough, from the Oxfo area, and would wish so to continue.

These boundary adjustments would be small, but a important because they chiefly affect areas which a apportioned to Bristol but are distant from it. Th would increase the population of the Oxford region about 300,000.

Some of our regional services (e.g., orthopædics) exte beyond the proposed boundaries; but in the light of t Ministry's circular we presume they will continue heretofore.

Cambridge

The region centred on Cambridge University compri the counties of Cambridge, Huntingdon, the Isle of El Norfolk, the Soke of Peterborough, and East and We Suffolk. Included within it are the county boroughs Norwich, Ipswich, and Great Yarmouth, and parts the counties of Bedfordshire, Rutland, Lincoln, Her fordshire, and Essex. It is clear that the populati will be $1^1/_2$–2 million.

The principal centres of population are Cambrid Peterborough, Norwich, and Ipswich, and these a separated from each other by large tracts of rich agr cultural land. The turmoil of the industrial revolutio affected East Anglia but little, and the growth of moder means of transport has not tended to produce dormito areas near the great centres of population describe On the other hand, the absence of large industrial centr has meant that hospital development throughout th region has been slow, and particularly the developme of municipal hospitals, with the result that gener hospital provision is inadequate, and certain speciali services are not readily available. The linking up of th principal centres will ensure that the best use is ma of hospital accommodation, and the development a expansion of specialist services in each centre can so coördinated as to prevent overlapping. For exampl Ipswich will become the focal point for the consulta services for the greater part of the counties of East a West Suffolk, sharing at the same time in the region developments in such special subjects as thora surgery, neurosurgery, and long-stay orthopæd units.

The region is fortunate in having Cambridge as i parent university. Plans are now well advanced for postgraduate medical school, and a number of spec departments are already in existence—e.g., patholog clinical biochemistry, radiotherapeutics, and expe mental medicine. Other specialties, such as hæmatolo and rheumatic diseases, will shortly be developed, a are to be followed by pædiatrics, dermatology, thorac surgery, and orthopædics. The defined region is large agricultural, and the investigation of diseases pecul to, or prevalent among, an agricultural community w be one of the tasks undertaken by the university resear departments.

In many respects the main part of the Cambrid region offers ideal facilities for coördinated and unifor development, and criticism of the Minister's propos can be restricted to the periphery. His desire th wherever possible the boundaries of the regional are should coincide with those of the local health authorit is presumably the reason for excluding almost the who of Essex and Hertfordshire, although the northern pa of those counties, being agricultural, have more common, in all respects, with East Anglia than wi London. It is in the northern part of the region, howeve that the most serious grounds for debate arise. There- no university centre between Cambridge and Sheffie and the latter university is required not only to de with a vast industrial population but also to extend i influence as far to the south-east as the farm lands

In England Now

A Running Commentary by Peripatetic Correspondents

"WALKING the hospital" was the term used in the past for the time spent in hospital after the student had served his apprenticeship with a general practitioner. Doubtless he walked much more than his successor, who arrives at hospital by bus, tube, tram, bicycle, or car. But "standing in hospital" would really have been more accurate. Forty years ago, when I entered hospital, the clerk or dresser was never allowed to sit down during ward rounds. These might go on from 1.30 to 4 P.M. or even later, and the physician, clerks, sister, and nurses, one of whom carried an inkpot and a quill pen, stood the whole time. The house-physician alone was privileged to rest one buttock on the locker, and history relates that one who worked for a very painstaking physician was found at 5 P.M. resting on the locker and reading Homer, while his chief was examining the patients in his usual careful way. In the operating-theatres the students used to stand as a rule, though they sometimes leant on the table to hold a struggling patient. Students were allowed to sit in outpatients and during lectures, but while waiting for the ward rounds to begin there was usually nowhere to sit. Doubtless this long standing was of value in learning to maintain a dignified carriage however tired the doctor might be, but it is difficult to see how it can aid the absorption of knowledge.

Nowadays in some hospitals the students are allowed to sit round the bed on stools or chairs, and I am sure that the rounds are not so exhausting as they were. I have never seen anyone fall asleep, as some students (I for one) do at a lecture however interesting it may be. I think the student's attention is less easily distracted when he is comfortable than when he is standing first on one foot and then on the other. Physicians seem more ready than surgeons to allow the clerks to sit down. The surgeon tends to go more quickly from bed to bed than the physician does, so the stools would have to be moved more often in the surgical rounds, but surgeons should at least try the experiment. Not all physicians allow stools, and the suggestion has been made that those who do so are currying favour with the students and thereby trying to attract large crowds. This is an unworthy accusation, for physicians as a whole prefer smaller classes where the clerks can examine the patients without too long exposure. Let us hope that the practice will spread and that standing in wards will become as obsolete as walking the hospitals.

* * *

When the business-end of a cow appeared through my office door followed by two-thirds of the animal my first reaction was to grab for the telephone in order to ring up J of the Public Works and say "I told you so." I had always argued that it was a mistake to build a ramp up to the office in place of steps. I decided, however, that it would be wiser to leave by the window before the remaining third of beef won the tug-of-war that was obviously taking place somewhere in the rear. At the top of the ramp a scandalised peon was holding on determinedly to the cow's tail, yelling for help, while just behind him a Hindu veterinary inspector and an unusually burly Bedouin were about to engage in a life-or-death struggle. Next minute a small army of orderlies, sweepers, and bearers went into action and the three actors in the comedy were pushed down the ramp and out into the safety of the yard.

Pandemonium then broke loose. Out of the babel of Arabic, Hindustani, and English I gathered that the Bedouin was complaining against an unjust decision of the vet. The latter said the cow was pregnant, and war-time regulations, still in force, forbade the slaughter of pregnant animals. The Bedouin maintained she was not, and, taking advantage of that cursed ramp, had driven the animal into my office so as to make sure that I saw her. When you sign on the dotted line for the Colonial Medical Service you can be sure of one thing—you will be frequently landed with some out-of-the-way job. My peculiar chore is administration of the Veterinary Department.

Unfortunately nobody has ever enlightened me as to the signs and symptoms of pregnancy in the cow. For once Macewen failed me and the number of rings on the horns or its classification as cow, heifer, stirk, or quey furnished no answer to the problem. So, keeping Solomon well in mind (after all, this is the Queen of Sheba's reputed embarkation point) I said the animal was to be slaughtered and if she was found to be pregnant the cattle dealer would be prosecuted.

Both parties were agreeable, so I accompanied them on their unpleasant mission to see fair play (Moslem abattoirs do not favour humane killers). While waiting the vet regaled me with endless tales of the dishonesty and general rascality of Arab cattle dealers, but even he was reduced for a moment to complete silence when a grinning butcher put out for our inspection a perfectly empty uterus. Then he found his voice again: "Sir, that she-cow has deceived me, but, Sir, she was so plumpey."

* * *

Have you noticed how few statues in London commemorate the achievements of those connected with medicine? There are more than a hundred statues dotted about in the open spaces and thoroughfares of the metropolis, and they celebrate the distinction of royalties, statesmen, explorers, soldiers, sailors, scientists, authors, artists, philosophers, and, last and least in number, nurses and doctors. Lord Lister looks benevolently down Portland Place. Sir Hans Sloane dignifies the physic garden in Chelsea though his treasures glorify the British Museum, John Hunter's bust is back again in Leicester Square near the site of his anatomy school, and the sculptured features of Miss Aldrich Blake, that noble-minded surgeon, grace the dullness of Tavistock Square. Near Waterloo Place, Florence Nightingale stands close to the statesman who was the means whereby she achieved her purposes in the Crimean war, while those who walk north from Trafalgar Square past St. Martin-in-the-Fields will find inspiration in the nobly resolute figure of Edith Cavell. The visitor to Kensington Gardens can see Jenner seated in sylvan surroundings frequented by the children whom he did so much to benefit. That completes the medical statuary of London streets, and I must confess that Nurse Cavell's is the only one which awakens in me feelings of reverence.

Apart from the statue of Miss Aldrich Blake there is no witness to those who have made the last fifty years the most memorable in the history of medicine, surgery, and pathology. Does that mean that the public do not appreciate our profession at its true worth? I do not think so. Rather it is considered that a statue is a poor way of perpetuating a personality. It is a cold lifeless thing. Though there may be grace of limb or even dignity of gesture, though the features may be correct in line and accurate in proportion, yet the eyes are without expression and the complexion is the mask of death. The Greeks often put colour and gilt on their statues; that would at least give some touch of life, but our taste prefers the bare coldness of the uncoloured stone.

Even when the statue is worthy of its subject it is often erected where it is impossible to see it to advantage—on top of a column or on a high plinth—or in a place where to stand and admire threatens one with instant death from the busy traffic. No; give me a portrait which shows us the eyes in all their colour and vivacity and recalls the complexion and expression as they were in life.

* * *

There was a young psycho of Staines
Who plugged his aunt in to the mains
  Saying "Two hundred volts
  Should screw up her loose bolts
And prevent her undressing in trains."

* * *

As a patient I am impressed by my previous ignorance of nursing. The nurses are wonderful but the system—! It seems that any initial enthusiasm is to be discouraged, intelligent coöperation replaced by discipline, and the whole set in a caste system reminiscent of a public school with an ascending scale of privileges based on length of stay. I'm afraid this system has been its own downfall. Treating women like naughty schoolgirls was always poor psychology, but now that labour is so short and they know that elsewhere they will be treated as adults it is self-extermination.

venient and sometimes unworkable in the case of the borough and county hospital services, and it cuts through the natural catchment area of the most important hospital centre on the South Coast.

The voluntary hospitals of Brighton and Hove provide a complete hospital and consultant service of a high standard, which now serves an area with a radius of about thirty miles extending equally into East and West Sussex. The area is homogeneous and easy of access for patients and their friends, since trains and buses converge on Brighton. The hospitals on both sides of the border are in some cases served by the same consultants. To divide Sussex, as is proposed, would leave Brighton and Hove, the acknowledged medical centre of the South Coast, on the extreme edge of the region.

To those who know Sussex, with its great health resorts and thriving towns, this appears unfortunate, and the case for including the whole of Sussex in the South-east region is obvious. In the first place it would make the South-west and South-east regions more nearly equal in size; secondly, Kent and Sussex would be grouped conveniently round four centres—Canterbury, Tunbridge Wells, Chichester, and Brighton. Brighton in the centre of the South Coast, with its natural hinterland, is the largest of these and has the greatest number of consultants; it would be wasteful and short-sighted not to use it to its full extent.

From Kent.—Though large in its population (which must be close on 4 million), this is a region which is relatively compact and accessible. It is bounded by the Thames Estuary, the Channel, and the county boundaries with West Sussex and Surrey. Except only in London, where the borough of Lambeth has been divided—presumably to allow of the inclusion of King's College Hospital—no existing local-government boundaries have been transgressed. In the whole of the area there are only four county boroughs (Brighton, Canterbury, Eastbourne, and Hastings), and none of these boroughs has provided hospital services that it would prove difficult to integrate into a regional scheme. Radially there are ample and easy communications between London and all parts of the region. Cross-country journeys by rail between different districts are more difficult, but road linkage is more than adequate. The boundaries exclude no large areas that normally find their hospital provision inside the region; nor, with the possible exception of Beckenham and Penge, are any included that would ordinarily look elsewhere for their services. These two districts in Greater London are geographically part of Kent; but in practice they have an orientation more towards Croydon and east Surrey than towards north-west Kent. Their inclusion in the South-east rather than the South-west region should not, however, present difficulty, particularly with King's College Hospital available as a focus for their reorientation.

On all these counts the South-east seems a well-conceived and workable region, once one has accepted two postulates—that the regions shall be limited to 14, and that there shall be quadrisection of London. From a purely local point of view it is this division of London, and its attachment in quadrants to large sections of the home counties, that is likely to give rise to most of the early problems of regional planning. The division of London necessarily breaks up the unity of the municipal services already provided. Hospitals—particularly special hospitals—will be unevenly divided among the different sections, and it may not be possible for some time for each region to be self-sufficient.

Administratively there is a danger that the board in all its affairs will be dominated by London. In all five sections from which the board will be constituted—the university, the medical profession, the local authorities, the public, and the voluntary hospitals—London will loom large, and the more peripheral parts of the region will undoubtedly watch fearfully lest they are unable to obtain that degree of autonomy that might have been theirs had the region been smaller, or had it been a self-contained area looking towards, but not absorbed into, London. They will hope that the very size of the region will necessitate the delegation of real power to the management committees, and that through these committees they may still retain an extrametropolitan corporate entity.

A NEUROSIS CENTRE

THE L.C.C.'s hospital service, like that of oth authorities, has been hampered by shortage of nurs and domestic staff, and many of the buildings have bee destroyed or badly damaged. Sir Allen Daley, in h 1945 report,[1] says that for these reasons many patient evacuated during the war had not yet returned a the beginning of this year. Despite these difficultie however, he is able to record a number of positi achievements.

In May of last year a 350-bedded neurosis centre fo returned prisoners-of-war was established at the Souther Hospital, Dartford. Some of the patients had been i P.O.W. camps as long as five years, and they lacke the confidence to mix socially and succeed in civilia work. To restore this confidence they were sent out t work under local employers for short periods each day they were usually given unskilled work unless they wer tradesmen, and change of occupation was permitte once a week. At work they were visited by a vocational psychologist and a nurse, who was responsible for liaiso between the psychiatrist and the employer. The valu of this arrangement lay not only in the experience o various occupations but also in the opportunities fo association with healthy workmen. Men who were likel to be discharged from the Army were seen, within two weeks of admission, by a disablement resettlement officer of the Ministry of Labour. At a later interview, just before the man left hospital, the D.R.O., aided by reports by the psychiatrist and vocational psychologist, helped him to decide on his future employment.

Altogether 1202 patients were treated at the centre during the eleven months that it was in being. The results were good, perhaps partly because the men were on the whole excellent material and partly because every resource for treatment was at hand. The report suggests that with growing difficulties in finding employment as the labour market becomes more stable, an increasing number of patients will need vocational guidance. The establishment of a neurosis centre in collaboration with the Ministry of Labour is proposed. Here outpatients fit only for sheltered employment would be separated from those who might respond reablement.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED NOV. 30

Notifications.—Smallpox, 0; scarlet fever, 1383; whooping-cough, 1878; diphtheria, 301; paratyphoid, 19; typhoid, 3; measles (excluding rubella), 6005; pneumonia (primary or influenzal), 745; cerebrospinal fever, 47; poliomyelitis, 18; polioencephalitis, 1; encephalitis lethargica, 0; dysentery, 58; puerperal pyrexia, 130; ophthalmia neonatorum, 61. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were no deaths from scarlet fever, enteric fever, or diphtheria, 2 (0) from measles, 8 (0) from whooping-cough, 64 (6) from diarrhœa and enteritis under two years, and 20 (3) from influenza. The figures in parentheses are those fo London itself.

The number of stillbirths notified during the week was 294 (corresponding to a rate of 30 per thousand total births), including 29 in London.

On Active Service

AWARDS

THE following appointments have been made in recognition of gallant and distinguished service in the field:

O.B.E.

Lieut.-Colonel G. T. M. HAYES, M.C., M.B. N.U.I., I.A.M.C.
Lieut.-Colonel P. W. KENT, M.B. N.U.I., I.A.M.C.

---

[1] London County Council: Interim Report of the County M Officer of Health and School Medical Officer for the Year 1 Obtainable from P. S. King and Staples Ltd., 14, Great Sm Street, S.W.1. Pp. 63. 2s.

I had thought it probable that postpituitary extract rted its antidiuretic effect chiefly through the tubular centration. However, normally the tubules in man concentrating urea, for example, to approximately ir maximum, and the urine excretion could not be uced to much less than 1 c.cm. per minute, as in the periments, without a reduction in the glomerular rate or a gross alteration in the tubular behaviour to non- and low-threshold substances.

It would be interesting to know how the glomerular rate and the tubular concentration separately varied ring the diuresis and its inhibition by emotion, renaline, and postpituitary extract. This could be imated for instance by determining the creatinine or ulin clearance (1) in the "resting" dog, (2) during inhibited water diuresis, and (3) in water diuresis hibited by adrenaline, emotion, partial compression of e renal artery, and postpituitary extract. It might possible in this way to distinguish between the echanisms of these antidiuretic factors.

BRIAN H. MCCRACKEN.

R.A.F. General Hospital,
St. Athan, Glam.

THE TITCHNER CASE

SIR,—Surely the world is going a little mad! In the cent Titchner case a child comes back from evacuation ith what are called "dirty habits." There is nothing ery peculiar about this, a distressing, tiresome, miserable ay of showing that you are out of joint with the world which you find yourself. After all, adults have headches and effort syndrome and colitis and get away ith it, and the child rather naturally displays its malontentment with a reversion to more childish ways. here have been hundreds of such cases. The majority f mothers after a period of alarm or anger and fruitless unishment seek advice, realising that while such ehaviour is "nasty" or "naughty" it still requires ome explanation, and failing an explanation mothers an only regard it as something about which they are gnorant.

In this case a hysterical wave of publicity colours the whole thing with a falsified glare, with a result that an ugly-looking crowd of men and women storm the house where this unfortunate child lived, and to show their protest at cruelty proceed to behave in a singularly cruel manner. One wonders how many of these same women would have considered it worth their while to call in and offer to advise Mrs. Titchner or take the child off her hands for a half day or even see if the local child-guidance clinic (and there is one) could give any useful advice. We don't seem to hear that anything of this kind, surely a natural reaction to a distressing situation, was ever offered or accomplished. Instead, still all in the name of mercy and justice, an entire family is broken up: a man and a woman are sent to prison, frantic with indignation. The rest of the children, who make no complaint, are sent to an institutional upbringing, about which we seem to have heard some rather harsh things said lately. But here comes the most remarkable feature of all—the unfortunate Jean is showered with toys, sweets, gifts of all kinds, and an embarrassing number of offers for foster-home care. Now everyone knows that it is the hardest thing in the world to find a good foster-home for child in need of one. People say the money isn't enough or that it is too much trouble or that their husbands wouldn't like it. Some of the children who need foster-homes are normal, happy children unlikely to be in any way as difficult as Jean Titchner, but the lack of good foster-homes constitutes one of the main reasons for having to allow children to grow up in institutions. However, in this case justice was done. Or was it?

How many people experienced in the care of children would care to be cross-examined on evidence obtained by questioning a child in the circumstances in which Jean found herself? How many stable children of her age could behave normally and respond normally in that glare of publicity? And we know from irrefutable evidence that Jean was not stable and couldn't adjust to normal family life. With the journalists sitting around over their morsels like carrion crows, we hear nothing of whether this child was observed quietly, living and playing with normal children. Only in this way could any real information be obtained.

There were times during the war when a display of public feeling was followed by an appropriate action. In this case the appropriate action seemed to be a desire to tear these ignorant and harsh parents limb from limb. Now the law has seen to it that they are punished, but it is difficult to see how separation from their family and imprisonment under protest can do very much to re-educate either of them to mercy and understanding.

It was once very appropriately said, "He that is without sin among you let him first cast a stone"; so now there should no longer be any difficulty in finding foster-homes for difficult children, at any rate in Camberwell. But will it have that effect? It seems to me that, as usual, the slate has been washed clean with the tears of humanity, but all to very little purpose.

London, W.1. MILDRED CREAK.

EPIDEMIC THROMBOPHLEBITIS

SIR,—Lieut.-Colonel Manson-Bahr and Dr. Charters (Sept. 7, p. 333) describe this condition in a number of patients, most of them suffering from venereal diseases. In favour of a virus origin, they found relative lymphocytosis, negative bacteriological findings, and a possible relation to infective hepatitis. Mr. Fisher and Dr. Lendrum (Sept. 21, p. 438), referring to a similar condition observed by them, describe a peculiar form of inflammation characterised by extreme proliferation of young capillaries in the disrupted media of the veins and by intracytoplasmic inclusions. Mr. Power (1946, i, 572) describes several cases of thrombosis of spermatic veins, and considers the ætiology obscure. This syndrome had been described as far back as 1908 by Aldo Castellani under the title "endemic funiculitis." All these vascular conditions were recorded in adults.

Thrombophlebitis and thrombo-angiitis of extremities in relation to lymphogranuloma venereum have been described by several authors. In a detailed study of arterial lesions in lymphogranuloma venereum we reported typical inclusions in damaged vessels.[1] Thrombophlebitis and thrombo-angiitis as single manifestations or subclinical forms of so-called non-specific epididymitis have been frequently observed by us in lymphogranuloma venereum (simple or associated urethrogenous penetration of the virus).[2]

In the cases studied in Africa and Ceylon by the British authors no mention is made of a typical inguinal bubo, because it did not exist, and therefore lymphogranuloma venereum was not investigated. With simple urethrogenous infection, or with simultaneous syphilitic or gonococcal infection, inguinal buboes may be atypical or absent.

When syphilis and lymphogranuloma occur together œdema of the prepuce is almost constant, thrombo-lymphangitis of the dorsal lymphatics of the penis or of the sulcus coronarius are very frequently present, and unilateral or bilateral deep iliac lymph-node enlargement is never absent. This last sign, which can only be found when sought, in our experience is almost pathognomonic of lymphogranulomatous genital infection.[3] In almost every such case the Frei test is positive, and microscopic findings in a very high proportion.[4] Rectal or buccal penetration of the virus must be kept in mind. General symptoms, such as fever, arthralgia, stiff-neck, &c., are not uncommon in lymphogranuloma venereum, which is a systemic disease.[5] In abortive or atypical forms (with absence of inguinal bubo) such symptoms seldom occur.

We have also observed epidemics of lymphogranuloma venereum, but almost always the source was found to be among prostitutes.

In 1934 we studied experimentally the possible importance of *Pediculus pubis* as carriers of the virus.[6] Skin over inflamed lymph-nodes is infiltrated and contains the virus, and antigens have been prepared from skin lesions. In 1939 Quintanilla-Braga[7] reported that pediculi might act as vectors of the virus.

Letters to the Editor

A MORAL PROBLEM

SIR,—Mr. Kenneth Mellanby states the case of those who believe that there is no inherent wrong in performing vivisection experiments on human beings without their consent, and perhaps in opposition to it. Alternatively he claims that those who would not do such things themselves are entitled to use knowledge gained thereby. He describes as "simply pernicious sentimentality" the opposite view that those who would use knowledge thus obtained are accessories after the fact and become responsible for the actions that gave rise to it.

He shows that there is no borderline at which to stop once the starting-point is passed. He classifies those who have done such experiments as "so-called scientists," "irresponsible sadists," and "serious research-workers." Yet who can say that everyone that works in a laboratory is an earnest seeker after truth, or that there never has been a vein of cruelty in any one of them? And has nothing been found in science except by those of "academic standing"? There is the same want of definition of those upon whom it is justifiable for such investigations to be done. It would seem that even after having accepted the idea that such persons "should be given the opportunity to serve as subjects for experiments" Mr. Mellanby must put in much hard thinking before he can draft rules under which a licence for such vivisection experiments might be granted.

With regard to the "results" of those which have already been done, Mr. Mellanby "would grade them as 'confidential' and make them available only to bona-fide investigators." But the great glory of science is that all knowledge gained by it shall be free to all the world. Is this to be set aside so that investigators classed, by some person or persons unknown, as "bona-fide" may have at their hand results of such research that possibly may be useful but which are hidden from the rest of the world? Useful to whom? To still more investigators? Or to us who are clinicians? We are scientists in that we must use the results of science in our pursuit of the art of healing. For this we must use our critical judgment. We must decide for ourselves whether the work of the investigators is good work and whether it is such that we can confidently recommend it to our patients or try it on them. To exercise this judgment we must have the whole story.

No! If this material is to be touched, it must be published in full. Then and then only shall we be able to judge how much there is of value in it. Then also shall we know the full story of the bestiality under which some, at least, was done, and be able to weigh the rest in the light of this.

Far better however would it be for the whole to be destroyed uncopied and unrecorded, as was indicated in the novel by Miss Josephine Bell to which you have already referred. This book tells of a certain hospital in which a number of persons had died mysteriously. The suicide of a member of the staff brought to light that these deaths had resulted from his injecting patients in a study of anaphylaxis which was then the problem of the day. His "work" was nearly finished. A meeting of the staff was called to decide what should be done with his records which they had before them on the table. One member—a pathologist—urged that they must be given to the world as they were of great importance. But the chairman—a clinician—held the opposite and swayed the meeting to his view. The papers were destroyed in the presence of them all. The words, quoted by you on Nov. 30, that Dr. Bell puts into the mouth of the senior physician will bear repeating: "May I remind you that our duty to our neighbour, our fellow man, comes before even our interest in science?"

T. B. LAYTON.

London, S.E.1.

SIR,—Dr. Mellanby's letter is a warning to those who say "it couldn't happen here," and of the dangers of being a "keen research-worker" with "little contact with the world outside his laboratory," and of "believing whatever his government tells him."

A. NELSON-JONES.

London, S.W.15.

THE ACT

SIR,—The controversy which is at present ragin about discussions with the Minister of Health has mad me ponder over the factors which would appeal both t the public and to the medical profession as evidence o an earnest wish on the part of the Minister, or a definit promise for better health and better treatment for th sick.

From the point of view of the public this would impl a levelling up of the treatment, especially among the les well-to-do, so that invalidism should be as short as possibl and recovery as complete as possible, while the illnes itself would be made as little unpleasant as might be.

On the preventive side of health we should first conside better houses and more houses in order to lessen overcrowding; better conditions of work with much les exposure to various industrial risks; and all thos measures which will provide better food and safer drin for everyone. It is of course extremely important t cater for adolescent and adult education, so that the greater leisure which machinery will bring can be usefull employed by all.

For the doctors there are many important factors, th first and the greatest of which is the increased facilit for acquiring a real knowledge of professional work s that each doctor may be able to treat his patients better This will largely mean help in various directions, includin (1) aids to diagnosis, and (2) help in treatment, which—whether the treatment be carried out in the patient's home or in an institution—means for the patient the ready acquisition of nurses, masseurs, and domestic helps, and for the doctor domestic helps, stenographers, and an attendant nurse. In hospital practice we need more beds, more domestic staff, more nurses, more porters, more stenographers, and more technical assistants, so that not only may the treatment be carried out more efficiently but everyone may have more time to devote to the care of the sick. This would make the work easier and would enable the doctor to get through his work more comfortably and to have leisure both for physical exercise and for reading, so that he would find it much simpler to keep up to date in his professional work, and at large would do his work better and under better conditions.

At present the doctor in hospital, and the practitioner doing general practice, works long hours, usually more than twelve hours a day. He does not get free weekends, for patients are ill both on Saturdays and Sundays, and he can never be sure of a night in bed.

Now the Act does not hold out any promise, either in the immediate or in the remote future, of providing any of the things which have been discussed; indeed the name of the Act is a misnomer for as it stands at present it is merely a measure for the nationalisation of the medical profession. The coördination and the control and the direction of the practice of medicine in all its branches will become more complete, but the patient is offered nothing. Even if the Act were to double the doctor's remuneration it would be unwelcome to the good doctor because it does not give him a chance to do better work under better conditions. The Act merely suggests more work for all and less rather than greater efficiency.

K. DOUGLAS WILKINSON.

Birmingham.

ABSORPTION AND EXCRETION OF WATER

SIR,—Prof. E. B. Verney's article (Nov. 23 and 30) throws considerable light on problems of variations in renal excretion.

He has endeavoured to demonstrate in dogs that the inhibition of diuresis by postpituitary extract contrasts with that of adrenaline because it produces a different graph of excretion; and he implies that adrenaline acts by reducing renal blood-flow, which is little affected by postpituitary extract. The suggestion is that normal physiological variations in urine flow are achieved by variations in posterior pituitary secretion.

Urine flow can be varied by one of two mechanisms: (1) the reduction of glomerular filtrate, and (2) water reabsorption by the tubules—i.e., tubular concentration. It is apparent that in diuresis due to decreased posterior pituitary secretion tubular concentration is diminished, since the concentration of solids in the urine diminishes;

hypertensive types. (Do acute tuberculous patients er have arteriosclerosis?)

Mr. Sampson Handley (Nov. 30) speaks truly of thology as necessarily dealing with "the body working a whole." He has seen 2 cases recently in which ronic cholecystitis preceded heart trouble. In the last ree days I have examined 3 subjects of sudden death. The first died two hours after taking ill: he had 8 pints of eural fluid, a heart weighing 27 oz., and a distended and flamed gall-bladder with adhesions. The second, said to ave been asthmatic, died four hours after taking ill; the eart weighed 28 oz., there were small white kidneys, and a all-bladder, very large, nearly black, and containing about 0 small stones like blackcurrants and 1 larger one impacted the cystic duct. The third had 6 pints of pleural fluid, a eart weighing 22 oz., advanced calcareous and atheromatous isease of the aortic ring and valves, and a malignant ulcer on he foot with secondaries in the inguinal glands, lung, and kidney; the gall-bladder had numerous adhesions around it. All these cases had coronary artery disease but no complete occlusion. Though they were obviously cases of chronic toxæmia there was no thrombosis. I do not know whether the infective agent was a staphylococcus.

Worthing. W. O. PITT.

SIR,—I should like to join in on the side of Mr. Sampson Handley (Nov. 30), and support his view that coronary disease is more probably due to chronic bacterial infection than to the "strain of modern life." Leaving aside the particular example of chronic cholecystitis and cardiac disease, of which I too have seen several examples, and also the cases of gall-stones erroneously diagnosed as coronary attacks, I would point out that the increased red-cell sedimentation-rate and the leucocytosis in coronary occlusion suggest the infective nature of the condition.

London, W.1. G. E. BEAUMONT.

SIR,—We are not likely to understand angina pectoris until we cease to regard it as a consequence of arteriosclerosis. For more than 25 years I have argued that arteriosclerosis is not a disease but a healing mechanism.[1] The disease whose ravages it repairs is arterial atony; in the atonic condition the arteries are damaged by circulatory stresses, and this damage is healed by calcification—a process analogous to the healing of tuberculous lesions or hydatid cysts. The first stage is the deposition of a plastic mass containing cholesterol, and subsequently calcareous matter is formed. The sclerosis is in fact a protection of the weakened arterial wall. All the suggested causes of arteriosclerosis—infections, intoxications, and physical and psychological influences—are conditions which first of all give rise to arterial atony.

Arteriosclerosis, usually with coronary calcification, has been found post mortem in 50% of war casualties between 20 and 30 years of age; yet these subjects had not suffered from angina pectoris. The fact that the proportion of deaths from arteriosclerosis is only 6% suggests that it is usually arrested, and that it is in fact curable. Its increased incidence in recent years and its prevalence among those who bear special responsibilities should provide a clue to prophylaxis.

London, W.1. J. PLESCH.

PSYCHONEUROSIS TREATED WITH ELECTRICAL CONVULSIONS

SIR,—In reply to Dr. Chapman, may I point out that I have neither said nor implied that *intensive* electro-convulsive treatment, as used by Dr. Milligan, is ethically right when applied to sufferers from melancholia. I said that convulsive therapy seems likely to take a permanent place in the treatment of melancholia (Nov. 16).

I would agree with Dr. Chapman that if in a case of psychoneurosis all the symptoms are removed, and the patient is made cheerful, coöperative, and happy, his psychoneurosis may be said to be cured, even if, as he says, there be a slight intellectual deterioration after treatment; but there is no satisfactory evidence in Dr. Milligan's paper that his patients were made cheerful and happy, and I would like very much to know how often the patient and his friends were warned before treatment that it might possibly be followed by slight intellectual deterioration.

London, W.1. J. NORMAN GLAISTER.

REGIONAL BOARDS

SIR,—"Your Correspondent of Nov. 9" in his letter of Nov. 30 points out clearly the danger of a medical-chief administrative officer. He has to my mind struck at the crux of the problem.

We have in Britain in the municipal system experienced the defects and failures of two chief medical administrative officers—the medical officer of health, and the *medical superintendent* of general hospitals. And we should do well to remember the lessons that such a system has taught us. A half-hearted attempt has been made recently by a few local authorities to infuse a little democracy in their hospital systems; but it has not amounted to much. The title of medical superintendent has been changed to medical director, and a medical staff committee has been set up. But what is grudgingly given away with one hand is taken away with the other, for the medical committee's advisory powers are either counterbalanced or cancelled out by those of the medical superintendent or medical officer of health, sometimes acting in unison, at other times separately. Moreover, these two executive officers always have the last word, and always have the ear of the chairman and members of the committee of management at the convenient and strategic moment. F.R.C.S.

EXERCISE AND CARDIAC HYPERTROPHY

SIR,—More than 25 years ago I remember the late Dr. Strickland Goodall saying, during one of his physiology lectures, that no-one whose heart did not show hypertrophy could hope to be a successful athlete.

Only recently I read a veterinary surgeon's opinion that lack of stamina and sudden death of horses in the hunting field were due to the out-of-season walking exercise which, though admirable in itself, did not produce cardiac enlargement, and that a hard daily gallop should be included to produce this effect. It would be interesting to know if there is any record of a schizophrenic (whose heart is always small) ever having been successful in long-distance or strenuous athletic events.

Keighley. WRIGHT LAMBERT.

LEFT TURN

SIR,—Dr. Brian Kirman's letter of Nov. 30 emphasises a fact which we older doctors and people in general do not appreciate. Dr. Dain and all of us around his vintage have experience of two different worlds—pre-1914 and post-1914. We know something of the freedoms, incentives, individual enterprise, and contentment (aye, even among the poor) of the earlier world; a world of good manners and gentility, and politically a world of social reformists. We also know the world of bad manners, low morale, general poverty, general discontent, and social revolution. We are therefore in a position to judge which is the better.

The younger men have only experience of a disturbed world, and not unnaturally want to improve it; with the spirit of speed in the blood they want to cure all the evils at one blow; and I think they really believe they've got the answer in Communism. The really inspiring efficiency of totalitarian war organisation, they believe, can be carried into a world at peace; and they are encouraged in it by men who have material axes to grind.

Dr. Kirman hopes to see us assessed by the public at our true worth to it. That is exactly what we are fighting for. The new proposition is that we be assessed by the Minister of Health; and when we are nationalised it is we who will assess the public, not it us.

St. Osyth. R. E. CLARKE.

SIR,—Dr. Kirman should try to remember that there are quite a number of good doctors who are quite as common as himself, in the inverted-snob, or proletarian, sense of the word, and yet who still wish to retain a measure of that individuality which has characterised our race, and which is not to be found in politically less evolved peoples. We just don't want, and in fact will not be press-ganged and highjacked into working for, a rapidly developing totalitarian State; and we only ask to be left to work, as always, as hard as we can, but where we want, and with whom we want; governed only by the unwritten but clearly understood ethical rules of our great profession, and answerable only to our patients, rich and poor alike.

London, W.1. GEOFFREY PARKER.

---

HEALTH CENTRES

Sir,—Last March, in drawing attention to a series of articles on Health Centres of Today, you said that you hoped to follow this with a further series on Health Centres of Tomorrow.

Sometimes the best of plans cannot be fulfilled, and the detailed work of collating material on such a new and complex topic as the “health centre” is likely to take up many precious hours. Nevertheless I feel sure that The Lancet will *not fail us on this crucial question*—the keystone of the National Health Service Act.

Time does not wait. The announcement of the regional areas for the regional hospital boards means that the Minister will not wait either. No single medical or political body of any standing has put forward concrete plans on the character of or the detailed content proposed for the health centres. Why is this so? If the Minister is not presented with considerable plans in an advanced state of maturity, how can he act wisely? Discussion around the fundamental principles governing the construction of a health centre has not even begun in the medical journals. I appeal to The Lancet to meet this crying need, as it has promised to do, and to meet it quickly.

London, S.E.12. P. W. Roe.

⁂ We hope to fulfil our promise early in the New Year.—Ed. L.

SYNDROME SIMULATING ACUTE ABDOMINAL DISEASE

Sir,—During the last three months we have seen 10 patients with symptoms the same as those described by Mr. Goldstone and Dr. Le Marquand (August 24, p. 267). The ætiology and pathology have, however, been differently interpreted.

These patients, British soldiers between the ages of 18 and 25, were admitted with a history of recent sudden onset of severe sharp pain in the right hypochondrium, worse on breathing. In half of them the pain radiated to the right shoulder, and in 2 also to the left hypochondrium. Except for slight general malaise there were no other symptoms. The temperature was 100–102° F, and the pulse-rate 90–100 per minute; the respiratory rate was not significantly increased.

On examination the only positive findings were slightly diminished movement and air entry in the right lower zone of the chest, and marked tenderness and guarding in the right hypochondrium; in 3 cases deep palpation in this area caused pain in the right shoulder. The upper part of the right rectus muscle was in spasm, and the tenderness appeared to be in the muscle itself rather than in the underlying structures. In 4 a localised, transient, but unmistakable pleural rub was heard in the right lower zone of the chest 1–3 days after admission. The rub lasted for 12–48 hours. After the initial pyrexia, which lasted not longer than 2 days, there were no further general symptoms, and the pain disappeared in 5–7 days.

Of these patients, 6 were admitted with a provisional diagnosis of acute abdominal disease and were thought to be suffering from acute cholecystitis, acute appendicitis, or a perforated peptic ulcer. There were, however, no other symptoms suggesting abdominal disease, and peristaltic sounds were always well heard. This emphasises the similarity between our cases and the patients with the “new abdominal syndrome” described by Goldstone and Le Marquand.

The investigations on each patient included examination of the urine, radiography of chest, white blood-cell count, and blood-sedimentation rate; no abnormality was detected.

In view of the symptoms and signs, especially the pleural rub, it is considered that the condition of these patients was akin to the benign dry pleurisy described by Scadding. In our series, however, it was the right lower parietal and the right diaphragmatic pleura which was chiefly involved. Furthermore, in view of the muscle tenderness, it would appear that the connective tissue of the muscles was also affected. Thus benign dry pleurisy and so-called epidemic myalgia are brought into the same symptom-complex, and it is suggested that the two conditions are in fact differing aspects of the same pathological process.

We do not think, therefore, that the symptoms i cases, in which the clinical picture was so similar, be caused by “abortive forms of perinephric sta coccal infection,” as suggested by Goldstone Le Marquand in their cases. We suggest that *clinical syndrome is caused by an inflammatory pr* probably of virus origin, affecting the pleura and ot connective tissue. The pain and spasm in the mus would thus be due to local changes and to refe impulses along the intercostal nerves irritated by inflamed pleura. Why this condition should m affect the right side is a question needing fu elucidation.

CORONARY DISEASE

Sir,—Each year I examine post mortem a considerabl number of persons who have died more or less sudden most of them are elderly—upwards of 60. It is rare t see one that has not some coronary artery disease, ev if that has not been the cause of death. It is not unc mon to see this condition at any age after childhood. an average I examine one subject a week who h died suddenly from coronary artery disease, with eit complete or nearly complete occlusion of the artery.

I am therefore very interested in Sir Maurice Cassidy Harveian oration; but I feel that it perpetuates a unfortunate confusion of terms. After speaking o “coronary disease” he goes on to talk of “angin pectoris,” and then of “coronary thrombosis.” H pleads for the abandonment of the terms “angi minor,” “angina innocens,” and “pseudo-angina saying that either the patient has angina or he has n He attributes the angina to ischæmia of part of th myocardium, usually the result of coronary ather sclerosis with or without coronary thrombosis or subliminal hæmatoma. (Here we have three new terms *He suggests that severe anæmia* alone, or probably wit some degree of atherosclerosis, may cause anginal pain and then he mentions the possibility of spasm of healthy coronary artery as a cause of coronary pain (Is this angina?) But he adds that physical examina tion may be surprisingly negative till coronary dis declares itself by the patient's sudden death. Su vasomotor angina occurs, he believes, without physi signs of cardiovascular disease and with a normal electro *cardiogram, and sometimes* with vasomotor instabilit flushing, or migraine. Later he begins to use the ter “coronary occlusion,” and thereafter talks regular of “coronary disease” and “coronary occlusion” wi one lapse to “coronary thrombosis,” though referri to the sudden deaths of miners in a certain series as d to “coronary atheroma.”

To overcome this confusion of terms I offer the follow suggestions:

1. Let “angina” be dropped altogether, or used only indicate a symptom.
2. Let “hypertension” likewise be used only to indicate physical sign. (It must always be due to increased resista to the flow of blood through the arteries.)
3. Let “coronary thrombosis” be dropped altogether as cause of death. (I have never seen a case in which dea was clearly due to thrombosis. When there is a thromb —and thus is rare—it is always in front of a mas degenerative matter.)
4. Let cases be described as “coronary occlusion,” parti or complete. (Due to accumulation of atheromatous calcareous matter, or commonly both.)
5. Let this be recognised as merely a local intensification of general arterial disease or degeneration. (Similar to cereb hæmorrhage or cerebral arterial occlusion—also erroneous called cerebral thrombosis—aneurysm of an artery, a perhaps some forms of migraine.)

If all these conditions were recognised as spec manifestations of arterial disease, their ætiology an prophylaxis would cease to be the exclusive province the cardiologist and neurologist. Investigators cou then concentrate on the causes of arterial disease, whi may prove to be some long-continued toxæmia, and mig thus be brought into line with other chronic toxæmi as in rheumatoid arthritis. It is an interesting possibili that there is an antithesis between the tuberculous a nurses and the domestic staffs engaged in tuberculosis ospitals.—Mr. J. STRACHEY replied: I am assured by my edical advisers that there are no medical grounds for granting xtra milk to nursing and domestic staff in tuberculosis anatoria.

Shared Staff

Mr. R. W. SORENSEN asked the Minister of Health, in view of he understaffing of nurses in some hospitals and the relative verstaffing in others, whether any consideration had been iven to the possibility of the temporary transference of members of the more fortunate hospitals to the less fortunate. —Mr. BEVAN replied: Some help is being given by the better-taffed hospitals on a voluntary basis, but nurses are no longer ubject to direction.

Birth Certificates

Replying to a question, Mr. BEVAN stated that he hoped o introduce this session a short Bill making it possible, as in Scotland, to issue, at a reduced fee, shortened birth certificates and also shortened extracts from the Adopted Children Register which will contain no reference to parentage or adoption.

Fluorine Hazard

Mr. C. WILLIAMS asked the Lord President of the Council e was yet in a position to say if the report on the fluorine ard near Port William would be published—Mr. HERBERT ORRISON replied: Yes, Sir, as soon as it is available

Chemical Standard for Ice-cream

Wing-Commander ROLAND ROBINSON asked the Minister f Food whether he would take powers to define a minimum hemical standard for ice-cream of at least 4% fat content, while retaining powers to review this standard when more at products were available.—Mr. STRACHEY replied: I should ike to fix a minimum standard for ice-cream; but I think his must wait until the supply of the necessary ingredients as improved For one thing I should not like to start with o low a standard as that referred to, and also fat is not the nly important ingredient in good ice-cream.

Atomic Research and Thames Water

Sir RALPH GLYN asked the Minister of Supply if he could make a statement in regard to the nature and condition of he water to be returned to the Thames after having been sed at the Atomic Energy Research Station, Harwell.—OHN WILMOT replied: All water returned to the Thames will comply with purity standards fixed by the Medical Research Council and already agreed by the other authorities oncerned. Most careful arrangements will be made to guard against any accidental discharge of radioactive water into the Thames.

Mr. WALTER ELLIOT, who last week took his seat in the House of Commons as M.P. for the Scottish Universities, is well fitted to represent a university constituency, for he is a graduate in science and medicine of the University of Glasgow, an honorary graduate of Aberdeen, Leeds, Edinburgh, Manchester, and South Africa, and has been rector of Aberdeen University He qualified in medicine in 1913, and during his service with the R.A.M.C in the first world war he was awarded the M.C. and bar In 1918 he first entered Parliament and five years later he was appointed under secretary for health for Scotland. Since then (till the last election) he has sat continuously in Parliament and has held many high offices. In turn he has been under-secretary for Scotland, financial secretary to the Treasury, Minister of Agri-lture and Fisheries, Secretary of State for Scotland, and om 1938 to 1940 Minister of Health During the late war, th the rank of colonel, he was for a time director of public lations at the War Office. He was elected F.R.S in 1935 C.P. in 1940. He is one of the founders of the new ociation of Agriculture, which happily reflects his interest th in the nutrition and health of the people

Drummond Young

Obituary

WILLIAM MURRAY HONEYMAN

M.B., B.SC. ST. AND., M.R.C.P.

Squadron-Leader W. M. Honeyman, who died on Nov. 24, entered St. Andrews University as first bursar, and graduated B.SC. in 1932 and M.B. with commendation three years later. After holding two house-appointments, he was awarded a Commonwealth fellowship and studied at Columbia University and at the Phipps psychiatric clinic in Baltimore. On his return from America in 1939 he was admitted to the membership of the Royal College of Physicians and became Halley Stewart fellow in the Medical Research Council's unit at Queen Square. At the end of the same year he joined the volunteer reserve of the R.A.F., and on mobilisation was seconded for duty to the psychological department of Cambridge University, where he worked on problems of applied neurology and psychology in aviation medicine till his tragically premature death.

"One could only admire in silence," writes D. D. R., "the fortitude and courage which sustained Willie Honeyman, so that even when his life was clearly on the ebb, he turned out reports illumined by all the clarity and insight of his fine intellect. Much of his work, for example his researches on after-contraction, was fundamental, but as he showed in his brilliantly ingenious study of the manipulative results of changes in the positioning of aircraft controls, he could respond to the challenge of an immediate practical problem. Had he gone on to full maturity he would certainly have justified the rich promise of his early career. Those of us who knew him well enough to appreciate the warm humanity which he disguised by a dry whimsicality, will remember him not only for his gifts of mind and heart but also for his intellectual honesty. He tolerated no scientific chicanery or humbug, and his merest nod of approval was praise indeed. For all this, and most of all for the inspiration of his conduct in the face of adversity, we shall be always grateful."

ALEXANDRINA MATILDA MACPHAIL

O.B.E., L.R.C.P.E.

Dr. Matilda Macphail, who died at her home in Edinburgh on Nov. 6, was a daughter of the manse, born in the Island of Skye in 1860, and to the end of her life she retained the slow, soft, pleasant intonation of the West Highlands. After studying medicine at the London School of Medicine for Women, she obtained the triple qualification in 1887, and went to India in 1888 as the first woman medical missionary of the Free Church of Scotland. After some years of pioneer work in Madras she founded the Christina Rainy Hospital, where most of her work was subsequently carried on, though the exercise of her skill often took her to the farthest parts of the Presidency. She also for a time supervised the work of the hospital at Conjeveram, and was active in the founding of the Union Mission Tuberculosis Sanatorium at Madanapalle. She was much interested in the Medical School for Women at Vellore, and after the 1914–18 war assisted for a time in the teaching there. Having been unable to obtain a passage back to India during the war, she offered her services to the Scottish Women's Hospitals, and in 1917 acted as chief medical officer of the Manchester unit for Serbian refugees in Corsica. Later, in 1918, she organised for the Scottish Women's Hospitals their tuberculosis sanatorium for Serbian soldiers at Sallanches in the Haute Savoie.

She retired from her long period of active missionary work in 1929. In recognition of her work in India she was awarded the Kaisar-i-Hind medal in 1912, with a bar in 1918, and the O.B.E. in 1930.

Although often hampered in the course of her life by physical disabilities Dr. Macphail never spared herself, and worked with untiring energy. She was greatly beloved and respected by a large circle of patients and friends, Indian and European, in whom she maintained a warm interest to the end of her life. She died after only a few days' illness, and not long before her death at the age of 86 she was able to travel south to visit friends in London.

B. R.

Parliament

FROM THE PRESS GALLERY

Care of Young Children

ON the motion for the adjournment on Dec. 6, Dr. **BARNET STROSS** declared that in his view provision for the care and education of young children under five had worsened as compared with the admittedly makeshift arrangements made during the war. The subsidy for the training of assistants under the Child Care Reserve had ceased; for some time trained nursery teachers had not been available, and equipment was not so good. But even the finest nursery, Dr. Stross continued, could only be a complement to, and never a substitution for, a home. In peace-time, he thought, we had no right to ask mothers of children under two to go into factories. Dr. **STEPHEN TAYLOR** quoted papers from the medical press showing that the incidence of respiratory infection and the absentee-rate in day nurseries for children under two was very high. Many children also did not gain weight satisfactorily. Children of that age, he felt, needed continuity of care, and in nurseries a change of worker from time to time was inevitable.

Mr. **SOMERVILLE HASTINGS**, F.R.C.S., suggested that though there was a great place for day nurseries and nursery schools in the future, children should spend only half their time there. Let the child go to the nursery while the mother was occupied with her household duties, but for the rest of the time the child should have the undivided attention which he claimed and needed. Mrs. **JEAN MANN** urged that a healthy happy mother was best employed looking after her own children, but added that she would like to see the nurseries extended to take in the children of mothers who were ill or being confined.

Mr. **C. KEY**, in his reply, stressed that in the development of these war-time nurseries the motivating force had been industrial, but under normal peace-time conditions the Government believed that the right policy was to discourage mothers of children under two from going out to work, to make provision for children between two and five by way of nursery schools and classes, and to regard day nurseries and daily guardians as supplements to meet special needs. But until normal times came, and while the needs of the home market and export had to be met, provision must be made for the children of mothers who were willing to go out to work. The welfare and local education authorities, after reviewing the needs of their areas, had continued 916 nurseries under their maternity and child-welfare powers as ordinary day nurseries, had converted 300 into nursery schools, and had closed just over 100. The Government were aware of the need to improve the training arrangements and to raise the status of nursery nurses, and all nurseries were being inspected in this connexion and they were about to review the salaries of nursery workers. Fifty ex-Service girls were being trained as nursery nurses under the vocational scheme of the Ministry of Labour and more were to follow. But there was, Mr. Key admitted, a shortage of staff, for one attendant was needed for every five children. The opening of nurseries in factories without reference to the welfare authority presented them with another problem, and he emphasised that it was not easy to adapt a war-time service of this kind to peace-time needs. He believed that the proper way of dealing with the children of mothers who were ill was by developing a system of home helps.

Priority Milk

On Dec. 3, on the motion for the adjournment, Dr. S. **JEGER** suggested ways in which the allocation of priority milk might be improved. The categories in the schedule for priorities were, he thought, too vague—dyspepsia and colitis, for instance, might mean almost anything, while other diseases, such as the anæmias, were absent. Industrial workers who were confined to bed should also, he believed, get some priority milk during the first ten days of their illness. He also pleaded for small families, old people who lived alone, and convalescent industrial workers. Certificates could now be given for either 14 pints or 7 pints a week. Could there not, he asked, be a new category of 3½ pints for such people as ambulatory gastric-ulcer and tuberculosis patients? Gastric-ulcer patients who received 2 pints of milk a day should, he thought, forfeit their meat ration. It would be easier for doctors if instead of giving the patients certificates for milk they gave statements of illness could be taken to the food office, where the decision whether milk should be granted would be made. D... cases could be submitted to a panel of doctors not in general practice.

Dr. **E. SUMMERSKILL**, in reply, pointed out that the priority categories had been established on the advice of the special advisory committee of the Medical Research Council and that they accounted for about 6% of the total consumption of milk in the country. She appreciated the difficulty the general practitioner sometimes had in refusing a certificate, and she thought that if a new category of 3½ pints were introduced it might seem to the doctor an easy way of moving a patient off the chair in the consulting-room, but they would certainly consider the suggestion. The gastric-ulcer patient if given the alternative between milk or meat would be constantly changing according to the state of his health. She regretted that it was impossible to adopt the suggestion of a committee to decide on eligibility for milk. No more work could be put on the food offices, and they would have to continue to leave the general practitioner to decide.

German Rations

The Chancellor of the Exchequer, in announcing the economic fusion of the British and American zones in Germany, said that the food ration of 1550 calories for the normal German consumer must be accepted for the present, but would be raised to 1800 calories as soon as conditions of world supply permitted.

QUESTION TIME

Closed Shop

Mr. J. A. **BOYD-CARPENTER** asked the Minister of Health what action he was taking to prevent the breakdown in hospital services threatened as a result of the action of the Willesden Council in directing that all nurses at their hospital who do not join a trade union will be dismissed.—Mr. A. **BEVAN** replied: I am sending a circular to local authorities pointing out that their primary duty as health authorities is to maintain the efficiency and smooth running of their health services and ensure the welfare of the patients for whom they are responsible. All other considerations must be regarded as secondary. While I am anxious that doctors, nurses, and members of similar professions should join a trade union or appropriate professional association, this is a matter which should not be determined by unilateral action of local authorities.

Dental Settlement?

Mr. J. **BAIRD** asked the Minister of National Insurance whether he was now in a position to make any statement about the dispute as to the terms on which dentists should undertake National Insurance work.—Mr. J. **GRIFFITHS** replied: A settlement has been reached on which the Joint Advisory Dental Council are recommending the profession to resume the dental benefit service forthwith. The terms of settlement, which the Government, the leaders of the profession, and representatives of the approved societies have agreed are fair to all parties, are as follows:

> As soon as the report of the Spens Committee on dental remuneration is available there will be negotiations between the Government and the dental organisations to agree in the light of the report two things: the method and order of remuneration of dentists in the National Health Service, and an appropriate scale of fees for work done under the present limited dental benefit scheme.
>
> If the scale of fees so arrived at shows that the present one was inadequate to meet the just claims of the profession, the Government will seek parliamentary authority for making payments retrospectively to dentists calculated to meet the difference between the amounts due to them for work paid for on the present scale from a current date and what they would have received had that work been done on the scale to be agreed.
>
> Pending the completion of these negotiations the scale of fees introduced by the Government on Sept. 30 will continue in force and will determine the payments to be made by insured persons entitled to dental benefit and by their approved societies.

Extra Milk for Sanatorium Nurses

Mr. E. A. **HARDY** asked the Minister of Food whether he was aware that nurses engaged in tuberculosis hospitals were not allowed a supplementary milk allowance except when nurses were suffering from tuberculosis themselves; and if he would arrange for a supplementary allowance to be given

itish Standards Institution

The 1946 yearbook gives a subject index and a synopsis of 1300 current British standards. The book is obtainable, ce 2s., from the institution, 28, Victoria Street, London, W.1.

nproved Water-purifying Tablets

The United States Army has been experimenting with ethods of individual water purification to replace the lorine-type tablet Triglycerine hydroperiodide has been und to answer to the requirements: quickly dissolved, safe, d effective, it can be used under a wider range of conditions, d causes a less objectionable odour and taste, than chlorine. rther trials with it will be made in the coming year.

onvalescent Home for ex-Servicemen

The British Legion convalescent and holiday home at hurchill Court, Sevenoaks, with accommodation for 50 x-Service men and women of the 1939–45 war, is now perating fully. The home is intended for those in need of:) convalescent treatment after a severe illness, or (2) a rtnight's holiday to prevent a breakdown in health. Applica-on should be made through the local British Legion Service mittee, or the British Legion and United Services Fund evolent Department, Pall Mall, London, S.W.1.

sociation of Industrial Medical Officers

A meeting will be held at the London School of Hygiene nd Tropical Medicine, Keppel Street, W.C.1, on Friday, an. 24, at 4 P.M. At 5 P.M. there will be a joint meeting with the chool medical service group of the Society of Medical Officers f Health, at which a discussion on the Change from School o Industry will be opened by Dr. A. A. E. Newth and Mr. D. T. A. Lloyd-Davies. At 10.30 A.M. on Saturday, Jan. 25, Mr. R. H. Young will give an address, illustrated by a film, n the Diagnosis, Pathology, and Treatment of Intervertebral Disks.

Dental Controversy Ended

The Joint Advisory Dental Council has recommended dentists to resume N.H.I. work forthwith. The statement by the Minister of National Insurance (reported in our Parliamentary columns) shows, says the council, "that the Government are fully prepared to accept an adequate scale of fees and to regard payments under the scale imposed by the ter as instalment payments only; that they are willing to negotiate what the fees should be as soon as the Spens Committee report is available; and that payments under any agreed scale will be made retrospective to the date of settlement." The council has been assured that the basis of settlement will not in any way prejudice negotiations on the method and order of remuneration under a future National Health Service.

New Operational Ration for the U.S. Army

Tests on American Army personnel have shown that men engaged in mountain climbing and mountain field work (described as moderate activity) expend about 3400 calories a day. This has prompted the U.S. Army to increase the "E" ration, which is intended for operational use over a period not exceeding 21 days, from 3331 to 3800 calories a ay. The new ration, weighing 5 lb. $3^1/_2$ oz., is composed of cans, 1 accessory packet, and 1 packet of 20 cigarettes with book of matches. The cans consist of 3 meat units of 12 oz. ach (there are 10 varieties); 2 biscuit units; 1 fruit unit h 4 varieties); and 1 bread unit, containing 4 oz. of bread. In the accessory packet are chewing-gum, n-opener, salt, wooden spoon, tablets for purifying drinking-ater, and tablets for heating the rations.

evision of Geneva Convention

A preliminary conference, attended by 141 delegates of orty-five national red-cross societies and by the League of Red Cross Societies, to revise the Geneva Convention, was eld at Geneva from July 26 to August 23 under the presidency f Monsieur Max Huber, president of the International Red Cross Committee. It was resolved to alter the wording of the convention so as to make it applicable to any outbreak f international hostilities, with or without a formal declaraion of war, and to civil war. It was also decided to extend he convention to cover all aspects of naval warfare, including he tonnage, routeing, and signals of hospital ships. Other mendations were to extend the protection of the red-oss flag to civilian sick and wounded, and to civilian hospitals countries at war; and to form non-military zones for the eatment of sick and wounded in such countries.

Airborne Medical Society

It has been decided to enlarge the membership to all medical and dental officers who are eligible for membership of the Airborne Forces Club, so that all medical and dental practitioners whose business it was or is to go to war by parachute or glider may now join the society. Quartermasters and transport officers of airborne field ambulances are also eligible. Application forms may be obtained from the hon. secretary, 63a, Belsize Park Gardens, London, N.W.3.

Maudsley Institute

The London County Council has approved in principle the recommendation of the Goodenough Committee that the Maudsley Hospital medical school shall be incorporated as a separate institute from the hospital within the British Postgraduate Medical Federation. Though a constituent of the federation the institute will have its own governing authority, academic council, and dean, and will be autonomous. But it will be financed from the University Grants Committee through the University of London on the recommendation of the federation. The L.C.C., except for its representation on the committee of management, will have no voice in the numbers of staff on the establishment of the institute, and it will pay for the services of the institute's staff who treat patients in the wards of the hospital.

Selective Localisation with Radioactive Isotopes

Radioactive isotopes show a tendency to settle in specific areas of the body, and may thus provide a new method of attacking neoplasms and other localised diseases, according to Dr. John L. Lawrence, of the University of California. "Radioactive carbon-monoxide, compounded with the short-lived isotope carbon 11, was gobbled up by the liver and held there for a while, before being released. We know that radioactive iodine 131 tends to settle in the thyroid gland. With larger than tracer doses it was possible in rabbits to remove their thyroid glands by slow selective radiation which destroyed the glands without damage to other tissues. Other isotopes concentrate in the bone-marrow, still others in the spleen. If we find such a compound for each vital organ, we can introduce it into the body and hit the abnormal area without damage to other organs. Ultimately," says Dr. Lawrence, "we might find a radioactive compound for each particular organ and for each particular type of cancer."

British Council for the Welfare of Spastics

A meeting was held at the London School of Hygiene on Dec. 12, with Prof. J. M. Mackintosh in the chair, to set up a council which will integrate all the activities in the United Kingdom directed to the welfare of adults and children suffering from spastic paralysis or allied conditions. The representatives invited included those of the Royal Colleges and various other professional bodies, the Ministries of Education, Health, Labour, and Pensions, the Department of Health for Scotland and the Scottish Education Department, the Ministry of Health and Local Government of Northern Ireland, the Board of Control, the ancillary medical services, the Trades Union Congress, London County Council, educational and welfare societies, St. Margaret's School, Croydon, and Birmingham Day School. The meeting was called to consider the constitution and trust deed recommended by a working party appointed at a previous meeting (*Lancet*, Oct. 26, p. 624), and to elect officers and an executive committee.

Pharmacists and the Act

About 170 million prescriptions a year will be dispensed under the National Health Service by chemists and health centres in England, according to Mrs. Irvine, vice-president of the Pharmaceutical Society of Great Britain, speaking on Nov. 27. Under present conditions, she said, it was unlikely that many health centres would be set up within the next five or ten years. That gave a fine start to the private shop and she hoped that before the Act came into force pharmacies would be equipped and staffed to deal with such an influx of prescriptions.

Mr. F. C. Wilson, of the society's council, has lately argued that if trade-union principles are followed, not less than four pharmacists will eventually be needed at each of the 5000 health centres he expects to see established. Since pharmacists on the register total only 25,000, there may, he thought, be some difficulty in obtaining them. "However the available number of pharmacists is distributed," he added, "there will be over double the number of patients for whom pharmacists will have to undertake dispensing, because . . . the functions of prescribing and dispensing are being permanently separated."

Notes and News

SCIENTIFIC REPORT OF ROYAL COLLEGE OF SURGEONS

During the first post-war year the college has been putting its house in order. The report for 1945–46 records that by last June all the anatomical specimens which had been evacuated to dispersal centres were back at the college; though here and there dampness had taken its toll, most were found to be in good condition. But a review of the specimens which survived bombing of the college has revealed heavy losses which can be repaired only by years of work and heavy expense; and the work cannot start until the department has been repaired and re-equipped. The department of pathology, after discarding some 1500 specimens, is left with 2800 specimens of value.

New light has been shed on body function in undernutrition by research teams working for Shaef in Western Holland and later for the Control Commission in Germany, under Dr. John Beattie, the Bernhard Baron research professor. Heat loss is regulated by nervous control of the skin vessels, while heat production, under conditions of rest, is controlled principally by the endocrines, which in turn may be influenced by nervous mechanisms. In starvation as seen in Western Holland the body temperature becomes stabilised at a low level, but the diurnal variations often exceed those in normal individuals. For the optimum rate of growth the calorie input must be constantly related to the input nitrogen; when the nitrogen input is doubled calorie input also has to be doubled to conserve as much as possible of the nitrogen. The later work in Germany showed that hunger-œdema is not, as was thought, due merely to hypoproteinæmia; it results apparently from a specific defect in the kidney induced by the deficient diet.

MEDICAL PHOTOGRAPHERS

Hospitals wishing to establish photographic departments have probably found difficulty in obtaining suitable technical staffs, owing to the lack of a recognised standard by which to gauge ability and experience. Institutions are understandably disinclined to pay high salaries for uncertain service, while photographers are reluctant to enter a field which offers no guarantee of a reasonable reward. Moreover, the few training centres have hitherto shown little inclination to run courses in medical photography. The decision by the Institute of British Photographers to set aside one part of their final examination to medical photography will thus be welcomed. A fairly comprehensive syllabus has been drawn up, and the first examination will be held in about twelve months. This action should help to place medical photography on a firmer footing.

U.S. ARMY CENTRE FOR THE DEAF

The United States army has established at Washington, D.C., an aural reablement centre for 250 "students" with impaired hearing. The unit, according to the *Journal of the American Medical Association* (1946, **132**, 219), will have its own laboratory, where dental technicians will make the ear-fitting moulds into which the receiver of the hearing aid is installed. The centre will have a staff of about 50, including 12 instructors in speech reading, 6 acoustic technicians expert in testing and fitting hearing aids, 6 technicians who will teach the use of the device, 5 speech correctionists, and smaller numbers of specialists in other fields. Students will remain about eight weeks. Major H. C. Barnaby, the director, has estimated that not more than 20% of deafness in the army is attributable to blast or other enemy action.

GOVERNMENT EMPLOYMENT FOR THE DISABLED

Under the Disabled Persons (Employment) Act, 1944, the Minister of Labour is empowered to provide opportunities for employment under special conditions of those who are unfit for other work. Accordingly, the Minister has formed a non-profit-making company, known as the Disabled Persons Employment Corporation, which has already established four factories—at Bridgend, Salford, Longton (Staffs), and Birmingham—and hopes to have a further four working by next April; altogether 48 factories, each employing 100–300 workers, are planned. Employees will be trained in wood, plastic, leather, and light assembly work, and, if competent, will be paid at the full trade rate. Special provision is to be made for epileptics and for the tuberculous; the factories will also supply materials and tools to workers who are fit only for employment in their own homes.

FILM CATALOGUES

The Scientific Film Association, of 34, Soho Square, W.1, has compiled two new catalogues. The first, a *of Films of General Scientific Interest* (5s.), lists in order over 600 such films available in Great Britain, from over sixty sources. For each film there are full of availability and a brief summary of content, while have in addition a useful appraisal of merit. A subject index at the back shows that over 100 of the films of medical interest. This will be a standard work of for teachers and programme committees. The *Catalogue of Films on Anæsthesia* (3s. 6d.), gives details films in loose-leaf format. For each film is given the catalogue number referring to the work shortly to be by the association in coöperation with the Royal So Medicine, the running-time, gauge, country and ye origin, distributor, and a two-line summary of the and purpose of the film. Next follow data on the used in presenting the material (whether diagram or ac studio-made or on-the-spot), an extended summary o film, in telegraphic style, and—most valuable of all—a critical assessment of the value of the film for purposes, based on the collective opinion of groups of selected by the association from all levels of interest: teacher, houseman, student, and nurse. It is obvious this system involves a great amount of labour, but the justify the trouble.

STETHOSCOPE AMPLIFIER

New Electronic Products Ltd., of 95, Station Hendon, N.W.4, are manufacturing an amplifier for use an ordinary stethoscope. Two alternative ranges, for ca and respiratory sounds respectively, can be emphasised reproduction is fairly faithful, even of breath sounds low a frequency as 25 cycles a second. Physicians presbyacusis might be well advised to equip themselves this instrument, which has the advantage of being co and inconspicuous. The price is about £40.

University of Cambridge

The faculty board of medicine have recommended appointment to the department of radiotherapeutics reader, and of a physicist with special reference to the app tion of electronics to radiotherapy. Mr. D. E. Lea, PH.D. Mr. H. F. Freundlich have been named for the posts.

On Nov. 30 the degrees of M.B., B.CHIR. were conferre M. C. Joseph (by proxy).

University of Dublin

On Dec. 4, at the school of physic, Trinity College following degrees were conferred:

M.D.—M. O'C. Drury, L. L. Griffiths, R. J. S. Wilson.

M.Ch.—H. A. Daniels.

M.B., B.Ch., B.A.O.—J. R. Bannister, D. S. N. Darling, D M. N. M. Dooley, M. E. Eppel, Robert Esler, J. P. R. F E. M. H. Forster, D. S. Kearon, P. J. MacCarthy, Esther M. Mc Eileen Moriarty, D. T. L. Nash, S. J. Poots, Brian Redmond, Robinson, Derek Anton-Stephens.

Licences in Medicine, in Surgery, and in Obstetric Sci Ivor Citron.

Royal College of Surgeons of England

Demonstrations in anatomy, applied physiology, pathology will be given at the college between Jan. March 28, from 10 A.M. to 1 P.M. and from 2 to 3.30 daily.

Course in Dairy Technology

A course of twelve lectures on Recent Advances in Technology is to be held at the Central Laboratories Express Dairy Co. Ltd., 133, Euston Road, N.W.1, at 6.3 on Tuesdays between Jan. 14 and April 1. Application be made to the Principal, Chelsea Polytechnic, M Road, S.W.3.

Francis Amory Septennial Prize

The American Academy of Arts and Sciences is of in 1947 this prize for outstanding work on diseases aff human reproductive organs published during the last years. No formal applications and no essays or tre should be submitted but the committee will welcome su tions from any appropriate source that will help the making a wise selection. Recommendations may be add to the secretary, Amory Fund Committee, American Ac of Arts and Sciences, 28, Newbury Street, Boston, M chusetts.

PNEUMOCONIOSIS IN SOUTH WALES ANTHRACITE MINERS

C. G. Gooding
M.D. Edin.
MEDICAL OFFICER, AMALGAMATED ANTHRACITE COLLIERIES LTD., AMMANFORD

This paper is based partly on clinical experience rovided by examination of many hundreds of anthracite niners during the last twenty years, and partly on the ecropsy findings in 592 deaths among certified silicotics*: 30 cases in which I was present at the necropsy, and 62 cases in which the necropsy findings were obtained rom medical colleagues, in particular Dr. T. W. David, hief medical officer, Amalgamated Anthracite Collieries td., or from the official certificates of the Silicosis Medical Board. The records of the company were also vailable for analysis.

CLINICAL FEATURES

In slighter grades there are very often no symptoms, and even in the advanced stage sometimes few or no symptoms.

The main symptom is *dyspnœa*, increasing with advancing damage to lung tissue and often augmented in older men by cardiorenal disease. In advanced stages dyspnœa may be present even at rest; but the disease develops gradually, and some men work right up to the end.

Cough is variable. In uncomplicated cases it is often absent or unproductive. Associated conditions, such as bronchitis and tuberculosis, may alter its features. *Sputum* may be absent or slight, even in some infected cases. Black spit, if persistent or recurring after an interval, indicates that the lung lesions are breaking down. *Pain* is not a significant feature, but there is often a history of past attacks of pleurisy. *Fever*, rapid pulse, wasting, and other toxic features develop only with added infection and not always then.

Physical signs are often slight, even with advanced lesions. Prolonged expiration, impaired percussion note, and reduced expansion are the commonest findings. As the disease advances, the air inspired may be so diminished that the respiratory murmur may be inaudible, especially in the presence of thickened pleura. Definite bronchial breathing suggests tuberculosis. Cavities, even when large, may not be clinically detectable. Adventitious sounds, dry and moist, may be present. Böhme (1939) emphasised as a diagnostic mark of severe silicosis the disproportion between the severity of the whole clinical picture and the slight signs found on percussion and auscultation in men with a history of adequate exposure to dust.

NECROPSY FINDINGS

The lungs are usually adherent to the thoracic wall, sometimes rendering their removal a strenuous operation. This adherence particularly affects the upper parts of the lungs, but basal adhesions too are common. Adhesions may be widespread or take the form of tough stringy bands. Often the pleuræ are much thickened. The surface of the lung may be smooth, but in advanced cases is more often distorted by puckering, most often in the mid or upper zones. Gross emphysema often gives the impression that the lungs are made up of many lobes, somewhat like a bundle of balloons.

The cut surface shows areas of fibrosis, black or blackish and varying in size from small discrete nodules, through patches of various sizes, up to very large areas of consolidation. In men who have worked consistently in hard headings—i.e., been much exposed to dust with a high content of free silica—it may present discrete nodules, as in "classical" silicosis, with little or no blackening; but such nodulation is often scanty and sometimes not apparent in the lungs of workers at the coal face, the massive type of fibrosis prevailing in colliers. Nodules in rock workers tend to be harder and more sharply defined than in colliers. The massive consolidations may be very large, of lobar dimensions or greater. In one case the normal lung tissue was so extensively replaced by massive fibrosis that I was almost forced to conclude that the patient had developed some extrapulmonary mode of respiration. These consolidated masses cut with a dry surface like solid black rubber. (One doctor jestingly says he uses this rubbery consistence as a test—"if the lung bounces, it is silicotic.") They may be solid and intact but often crumble and disintegrate and are often extensively excavated and filled with liquid or semi-liquid inky material. This material, if it escapes to the air tubes, provides the black spit of silicotic coalminers. Sometimes a whole upper lobe which appears from the surface to be solid is found on incision to be a thick-walled bag of this inky material. Lymph-glands about the lung root are usually enlarged, black, and fibrotic.

ASSOCIATED CONDITIONS

Tuberculosis.—Liability of "classical" silicotics to develop pulmonary tuberculosis is notorious; and, when the "classical" silicotic dies of his disease, tuberculosis is a usual accompaniment. Certain groups of colliery workers who worked consistently in hard headings (tunnelling through rock) provide a parallel to this, but there is less agreement about the incidence of associated tuberculosis in the pneumoconiosis of ordinary coalminers. There are in these cases even more obscuration and modification of the tuberculous element than in the classical silicosis of South Africa, and it is often difficult to recognise tuberculosis in these cases, even in microscopical sections.

Sometimes tuberculosis was evident in lung tissue adjacent to the fibrotic patches, where it had seemingly escaped the trammels of the pneumoconiotic lesion and flared into a tuberculous bronchopneumonia. Sometimes there was a cluster of tubercles adjoining a fibrotic lesion; very rarely a more general miliary distribution; sometimes a more chronic fibrocaseous lesion. In other cases tuberculosis was recognised by greyish mottling of some part of the fibrotic area or by a glandular lesion. Occasionally a case showing features suggesting, perhaps only faintly, tuberculosis in the lung was unmasked by meningeal or abdominal tuberculosis. In some patients whose sputa had been positive it was very difficult to recognise tuberculosis at necropsy.

Belt and Ferris (1942) remark that in a group of cases of identical appearance the tubercle bacillus would be found in one and not in another, but they were inclined to regard all the massive disintegrating lesions as phthisical, and suggested the name coniophthisis for the special type of lesion arising from the dust plus tubercle effect, "characterised," as they say, "by a reaction more fibrous, less cellular, more chronic-looking, and more widespread, obscured by a heavy dust deposit present sometimes even in the caseous parts of the lesion, with cavities more heavily encased in solid tissue and less voluminous than those of ordinary phthisis, and with few tubercle bacilli." It is not surprising that tuberculosis so lacking, as in these cases, in its usual clinical features should be correspondingly difficult to detect at autopsy, and in his series of 42 Belt detected the tubercle bacillus in only 8, and in 13 others with lesions of identical appearance he failed to detect the bacillus.

In my series of 230 necropsies tuberculosis was recognised in 59, just over a quarter, but disintegration and cavitation of the fibrotic lesions were noted in many

---

* Most of the patients who died had been certified under the pre-1943 schemes as "suffering from silicosis."

Exhibition of Ethiopian Art

An exhibition of Ethiopian art and industry is to be held at Foyle's bookshop, Charing Cross Road, W.C.2, from Jan. 20 to Feb. 4. Those willing to lend exhibits are asked to communicate with Miss Sylvia Pankhurst, hon. secretary of the Princess Tsahai Memorial Hospital Council, 3, Charteris Road, Woodford Green, Essex.

Allied Awards to British Officers

The President of the United States has conferred awards on the following medical officers in recognition of distinguished services in the cause of the Allies.

Legion of Merit.—Surgeon Rear-Admiral Sir GORDON GORDON-TAYLOR, K.B.E., C.B., Brigadier H. L. GLYN HUGHES, O.B.E., D.S.O., M.C. (degree of commander); Colonel F. S. GILLESPIE, Lieut.-Colonel A. N. B. ODBERT, O.B.E. (officer); Surgeon Lieut.-Commander A. P. CURTIN, Colonel THOMAS YOUNG, O.B.E. (legionnaire).

Medals.—Lieutenant J. D. DEVITT (silver star); Wing-Commander EDNA BUTLER-JONES, Brigadier M. L. FORMBY, Captain T. W. RENTON, Lieutenant J. G. SEARLE (bronze star).

Typhus Commission Medal.—Brigadier R. W. GALLOWAY, C.B., D.S.O., Brigadier G. S. PARKINSON, Colonel H. D. CHALKE, O.B.E.

The Prince Regent of Belgium has appointed Major-General Sir Edward Phillips, K.B.E., D.S.O., M.C., a commander of the Order of the Crown.

The Queen of the Netherlands has appointed Major G. F. Bramley and Major Harold Kennedy, M.B.E., knight officers of the Order of Orange Nassau with swords.

Appointments

BROWN, ARNOLD, M.B. Manc., D.P.H.: M.O.H., Cheshire.

CAHILL, JOHN, B.SC. N.U.I., M.R.C.S.: senior assistant M.O., Middlesbrough school health service.

EDINGTON G. M., M.B. Glasg.: M.O., Gold Coast.

ELDER, C. L., M.B. Glasg., D.P.H.: M.O.H., St. Albans.

GILLAM, G. G., M.D. Lond., M.R.C.P.: senior physician, Selly Oak Hospital, Birmingham.

HARTLEY, L. B., M.B. Camb.: ophthalmic surgeon, Woking Victoria Hospital.

LEIGH, A. G., M.D. Lpool, F.R.C.S.: surgeon to ophthalmic department, National Temperance Hospital, Hampstead.

ORMISTON, GEORGE, M.D. Edin., M.R.C.P.E.: pædiatrician, Southampton Children's Hospital and Royal Hampshire County Hospital.

PARTINGTON, C. N., M.B. Lpool: assistant bacteriologist and pathologist, Staffs.

PLUMMER, N. S., M.D. Lond., F.R.C.P.: physician, Edenbridge and District War Memorial Hospital, Kent.

PUGH, D. L., M.R.C.S.: assistant T.O., Kent.

RINKEL, L. R. J., M.R.C.S.: medical superintendent, British Legion Sanatorium, Nayland, Suffolk.

RONALD, JAMES, M.D. Edin., F.R.C.P.E.: assistant physician, Stirling Royal Infirmary.

ROSS, C. M., M.B. Edin., D.PSYCH.: deputy medical superintendent, Gateshead Mental Hospital, Northumberland.

SMITH, G. G., M.R.C.S.: M.O., British Honduras.

SPALDING, J. E., M.S. Lond., F.R.C.S.: surgeon i/c Wrexham Emergency Hospital, Denbighshire.

STRATTON, G. B., M.R.C.P.: temporary assistant M.O.H., Wimbledon.

Chesterfield and North Derbyshire Royal Hospital:

GRAHAM, J. M., M.B. Sheff.: visiting anæsthetist.
HERBERT, G., M.B. Camb., F.R.C.S.: assistant visiting surgeon.
MUIRHEAD, H. C., M.R.C.S.: assistant ophthalmic surgeon.
NICOLL, E. A., M.D. Camb., F.R.C.S.E.: surgical director of accident service.
POOLER, H. E., M.B. St. And., D.A.: visiting anæsthetist.
TAYLOR, V. J. M., M.B., M.CH.(ORTH.) Lpool, F.R.C.S.E.: orthopædic surgeon.

Dudley Road Hospital, Birmingham:

DISNEY, M. E., M.D. Lond., M.R.C.P.: senior physician.
FERRIMAN, D. G., D.M. Oxfd, M.R.C.P.: senior physician.
HEARN, G. W., M.D. Lond., M.R.C.P.: senior physician.
MAY, K. S., M.D. Lond., M.R.C.P., D.L.O.: senior physician.

Hospital for Sick Children, Great Ormond Street, London:

BODIAN, MARTIN, M.D. Vienna, L.R.F.P.S., D.C.P.: morbid anatomist.
HULBERT, K. F., M.B. Lond., F.R.C.S., D.A.: orthopædic registrar.
MACNAB, G. H., M.B. Edin., F.R.C.S.: surgeon.
MATTHEWS, D. N., O.B.E., M.D., M.CHIR. Camb., F.R.C.S.: plastic surgeon.
NASH, D. F. E., F.R.C.S.: surgical registrar.
NEWNS, G. H., M.D. Lond., M.R.C.P.: physician to outpatients.
SHARP, H. S., M.B. Camb., F.R.C.S.: surgeon to ear, nose, and throat department.
WALLACE, E. N. K., M.B. Lond: outpatients aural registrar.

St. Mary's Hospital for Women and Children, Plaistow:

BLACKBURN, F. H., M.B. Durh., D.A.: anæsthetist.
BLUNN, D. R., M.R.C.S., D.A.: anæsthetist
JOAD, M. M. G., M.R.C.S., D.A.: anæsthetist.

Examining Factory Surgeons:

DELAP, P., M.B Dubl.: Appleby, Westmorland.
HUGHES, W., M.R.C.S.: Ashton-in-Makerfield, Lancs.
REID, A. C., M.B., B.SC. Edin.: Almondsbury, Glos.
ROBERTS, W. H., M.R.C.S.: Buckfastleigh, Devon.

Ministry of Health:

Medical Officer

MACFARLANE, JAMES, M.B., B.COMM. Edin., D.P.H., M.O., Department of Health for Scotland, seconded to the Ministry of Health.

Diary of the Week

DEC. 15 TO 21

Monday, 16th

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8.30 P.M. Sir James Chadwick, F.R.S.: Atomic Energy a Applications to Medicine. (Lloyd Roberts lecture

HUNTERIAN SOCIETY
7.15 P.M. (Pimm's, 3, Poultry, E.C.2.) Dr. Geoffrey Flatulence.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. A. D. Porter: Vitamin A in Dermatology.

Tuesday, 17th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. R. W. Raven: Melanoma and Related (Erasmus Wilson demonstration.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8 P.M. *Pathology.* Thrombosis: Mr. H. J. B. Atkins aspects); Dr. R. H. B. Short (pathology of primary bosis): Dr. Helen P. Wright (platelet changes) H. P. Gilding (anticoagulants).

EUGENICS SOCIETY
5.30 P.M. (Royal Society, Burlington House, Piccadilly, Dr. J. W. B. Douglas: Social and Economic Childbearing in Britain: Report of a Q Inquiry.

LONDON SCHOOL OF DERMATOLOGY
5 P.M. Dr. H. Corsi: Diseases of the Nails.

Wednesday, 18th

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Place, W.1
3.30 P.M. Dr. C. H. C. Toussaint: Tuberculosis—the O and its Approach.

Thursday, 19th

ROYAL COLLEGE OF SURGEONS
5 P.M. Dr. E. Ashworth Underwood: Naval Medicine in th of Elizabeth and John. (Thomas Vicary lecture.)

ROYAL SOCIETY OF MEDICINE
5 P.M. *Dermatology.* Cases will be shown at 4 P.M. Dr Hohmann (Groningen): Erythematous Initial Tuber

Births, Marriages, and Deaths

BIRTHS

BALY.—On Nov. 30, at Hillingdon, Middlesex, the wife of Dr Baly—a son.

BLACK.—On Nov. 30, in Leeds, the wife of Mr. George Black, F.R —a daughter.

COOMBS.—On Dec. 2, the wife of Dr. Gordon Coombs, of Ho Norfolk—a daughter.

CORBIN.—On Dec. 4, the wife of Mr. John O. Corbin, F.R.C. Cudham, Kent—a daughter.

DE SOLDENHOFF.—On Dec. 2, in Ayrshire, the wife of Mr R de Soldenhoff, F.R.C.S.E.—a son.

HARRIS.—On Nov. 22, at Langport, Somerset, the wife of Dr. Harris—a daughter.

HORNE.—On Nov. 26, at Hampstead, the wife of Dr. N. C. —a son.

LLOYD.—On Nov. 30, at Tenterden, the wife of Dr. T. W. Ll a son.

MACKEITH.—On Dec. 2, the wife of Dr. R. C. MacKeith—a

PUGH.—On Dec. 6, the wife of Dr. David W. Pugh, D.S.C.—a d

TUCKWELL.—On Dec. 3, at Compton, Guildford, the wife o Edward Tuckwell, F.R.C.S.—a son.

TWEEDIE.—On Nov. 15, at Batu Gajah, Malaya, the wife of Reid Tweedie—a son.

VENABLES.—On Dec. 6, in London, the wife of Dr. Peter Vena a son.

WALSH.—On Nov. 25, in London, the wife of Dr. J. J. W a son.

WARD-MCQUAID.—On Dec 2, in Amman, Transjordan, the w Major Neil Ward-McQuaid, R.A.M.C.—a daughter.

WILLIAMS.—On Dec. 9, at Hampstead, Dr. Joy Williams Jowson), the wife of Dr. Denis Williams—a daughter.

MARRIAGES

CLARKE—*HEPBURN.*—On Dec. 5, at Worplesdon, Edward Clarke, M.C., B.M., to Patricia Hepburn.

NEVIN—DENNIS.—On Nov. 20, in London, Henry Millar Nevin, to Josephine Irene Dennis.

DEATHS

BAYLIS.—On Dec. 6, at Horns Cross, N. Devon, Henry Ed Montgomery Baylis M.B. Durh.

BROWNLIE.—On Dec. 4, in Glasgow, John Douglas Bro M.B. Glasg., F.R.F.P.S.G., L.D.S.

GRAHAM-JONES.—On Dec. 6, at Dorchester, John Lawrence Gra Jones, M.B. Camb.

HEWITT.—On Nov. 24, at Redhill, Harry Edward Hewitt, O M.D. Lond., D.P.H., aged 73

PRYCE.—On Dec. 6, at Welshpool, Harold Vaughan P M.B. Camb., F.R.C.S.

SMITH.—On Dec. 3, at Reading, George MacIver Campbell S C.M.G., M.B. Aberd., M.R.C.P., lieut.-colonel I.M.S.

IN recognition of his services to merchant seamen. Percival Cole has been made an honorary life member of Seamen's Union. Mr. Cole has been associated with Dreadnought Hospital for 35 years, and he was for man surgeon to the Tilbury Hospital and Queen Mary's Ho for East London. He is at p Hospital.

TABLE I—MODES OF DEATH IN 227 CASES

Category of certificate	Mode of death			
	Tuberculosis	Non-tuberculous respiratory affection	Cardiac failure	Unrelated causes
ilicosis plus tuberculosis	14	..	2	..
ilicosis—partial disablement ..	4*	4	9†	19
ilicosis—total disablement ..	36	34	64	24
ertified at death only	5	3	9	..
Total.. ..	59 (26%)	41 (18%)	84 (37%)	43 (19%)

* Excluding 2 cases later certified totally disabled.
† Excluding 3 cases later certified totally disabled.

here it has been attributed to radioactivity or to rsenic.

In this series of 230 cases there was only 1 case of lung umour; this was in a man aged 68 and was secondary to an abdominal new growth. Other sites of neoplasm were brain (1), pharynx (1), stomach (4), bowel (3), the men ranging in age from 49 to 68 years. Further, in other cases making with this series a total of almost 400 necropsies, I have noted the following 3 instances of primary lung cancer:

(1) A man, aged 58, with minimal dust changes and refused a certificate by the Silicosis Medical Board.
(2) A man, aged 55, with fairly advanced silicosis
(3) A man, aged 42, with no fibrosis of lungs (accidental death).

There was, therefore, only 1 case of primary lung cancer associated with pneumoconiosis of coalminers. In view of the fact that nearly all silicotic miners who come to necropsy have reached the cancer age, this low incidence suggests that there is no linkage of cause and effect between coalminers' pneumoconiosis and primary lung cancer. Any increased susceptibility of the silicotic to lung cancer has been attributed to silica, and perhaps a higher incidence might be found in workers exposed to high concentrations of the dust of free silica, but the Miners' Phthisis Medical Bureau of South Africa (1944) have reported that lung cancer does not appear to be more prevalent among silicotic than among non-silicotic miners or even men working above ground. Vorwald and Karr (1938) found no increased incidence of pulmonary carcinoma in persons exposed to industrial dusts as compared with the general population.

MODES OF DEATH

In their report on chronic pulmonary disease in South Wales coalminers, Hart and Aslett (1942) give the result of a canvass of general practitioners in the anthracite area in the statement that "cardiac failure and non-tuberculous respiratory affections are common clinical causes of death, while clinical tuberculosis sometimes occupies this rôle." These authors emphasise the comparative infrequency of clinically recognisable tuberculosis, the frequency of cardiac failure, and the opinion of local doctors that severe wasting is common terminally. In connexion with these statements the following analysis of 230 deaths is of interest (cases are arranged in four groups according to the category of certification):

"Silicosis accompanied by tuberculosis"	16
"Silicosis—totally disabled"	161
"Silicosis—partially disabled"	41
Certified at death only	17
Total	235

The excess of certificates over deaths is due to 5 "partial" cases having been subsequently certified "totally disabled."

Silicosis Plus Tuberculosis.—There were 16 cases: 14 confirmed post mortem, and 2 not confirmed and dying of congestive heart-failure.

Silicosis.—"Total" and "partial" cases, and those certified at death only, revealed no significant difference in their modes of death, except that among "partial" cases a greater proportion died from causes unrelated to silicosis.

Of 41 "partial" cases 5 later graduated to the "total" grade, and 19 of the remaining 36 died of unrelated conditions.

Of 161 "total" cases 24 died of unrelated causes, and 3 were an odd assortment: 1 dying shortly after developing pneumothorax, 1 after operation for insertion of radon needles in a pharyngeal new growth, and 1 dying suddenly with gross aortic valvular and myocardial disease, the Silicosis Board regarding silicosis as a contributory factor.

Omitting the 3 odd cases, the incidence of the various modes of death was as follows:

59 (26%) had associated tuberculosis.
41 (18%) had non-tuberculous respiratory affections.
84 (37%) terminated in cardiac failure.
43 (19%) died of unrelated conditions.

These figures are given in table I. All cases are included under the heading of tuberculosis wherever this condition was recognised, even though some of the tuberculous patients appeared to die from congestive cardiac failure rather than from the toxic effects of tuberculosis.

AGE AT CERTIFICATION AND SURVIVAL PERIODS

For consideration of these points my personal series of 230 deaths has been supplemented by 362 others, making a total of 592 cases for analysis. Of these, 66 were certified at death only. Table II deals with the remaining 526 cases, giving category of certificate, average age at date of certification, and average period of survival.

For "partial" cases both the average age at certification and the average period of survival in table II are anomalous. The average age at certification is too high, being raised by a considerable proportion of old men certified partially disabled by silicosis, often with total disablement from other causes, who had various diseases incident to advancing age. As the silicosis in these men was often of minor, sometimes of minimal, degree, and their fatal conditions were usually chronic, these older men probably sought certification because diseases of natural origin had brought their working life to a close. In the 41 cases of my personal series the respective ages at certification and survival periods for the two groups, "silicotic deaths" and "non-silicotic deaths," were 51 and $4^{1}/_{2}$ years, and $55^{2}/_{12}$ and $2^{4}/_{12}$ years.

TABLE II—AGE AT CERTIFICATION AND SURVIVAL PERIODS OF 526 SILICOTICS IN DIFFERENT CATEGORIES

Category of certificate	No. of deaths	Average age at certification (years)	Average survival period (years)
Silicosis (or pneumoconiosis)—totally disabled	370 (*70·3%*)	53	$4^{8}/_{12}$
Silicosis (or pneumoconiosis)—partially disabled ..	103 (*19·6%*)	54	$3^{10}/_{12}$
Silicosis (or pneumoconiosis) plus tuberculosis ..	53 (*10·1%*)	$45^{7}/_{12}$	$1^{10}/_{12}$

The true average age at certification for "partial" cases is 46 years, as shown in the last column of table IV, based on all certified cases of a large group of collieries and giving the age-distribution of all cases according to the category of the certificate: "totally disabled," "partially disabled," and "certified at death only."

The survival period is also anomalous, being unduly lowered by the older men mentioned above, and gives a false value for the expectation of "partial" cases, because it refers only to cases other than those recognised as tuberculous. Many pathologists do not regard this crumbling and cavitation as necessarily due to tuberculosis (Cummins and Sladden 1930, Cooke 1932, Gough 1940), but Belt and Ferris are not inclined to regard them as formed by disintegration of fibrous tissue, and think they are more probably necrotic from the first. Extensive lesions may show little or no disintegration or liquefaction, and relatively small lesions may show softening and breakdown without obvious tuberculosis. To a great extent opinion will depend on the criteria of diagnosis. If demonstration of the tubercle bacillus is insisted on, the tuberculous nature of these lesions in many instances cannot be proved, for very prolonged and thorough search of many sections may be necessary for its discovery. The comparable difficulty of detecting the bacillus in sputum may be noted. There is, however, an increasing tendency to regard infection as a factor in the production of these massive lesions. In this connexion it must be remembered that infection which was originally an important element in the disease may have retrogressed, and sometimes at necropsy an old apparently healed tuberculous focus is found with a black fibrotic shell surrounding it, without any silicosis of general distribution.

Wasting and other toxic features of tuberculosis were not constant, even when tuberculosis was obvious post mortem. Wasting is often difficult to estimate, but family doctors were usually present to give information on the point. It was exceptional in earlier stages of the disease, unless there was some associated wasting disease. Apart from this, only 1 case of 36 certified "partially disabled" exhibited wasting. It was more common among men with advanced silicosis. Of 161 cases certified "totally disabled by silicosis" wasting was present in 61. Of these, 25 had tuberculosis and 8 malignant disease; 14 had non-tuberculous respiratory affections, and these, together with the remaining 14, all had massive confluent lesions with much necrosis and disintegration of the masses but no recognisable tuberculosis.

Of the 230 cases 59 were ranked as tuberculous on necropsy, and 39 of these showed appreciable wasting.

Uncomplicated silicosis, therefore, even with massive lesions, does not in most cases cause gross wasting, and even of the tuberculous cases found post mortem a third did not show wasting.

Amor (1941) has suggested that the massive lesions are always accompanied by toxic symptoms. This is not borne out by my observations, many cases with massive crumbling lesions showing no toxic features even when there was a recognisable tuberculous element present; but all cases showing wasting and other toxic features had such lesions, apart from those with other wasting disease, such as carcinoma.

A noteworthy feature of the massive lesions was that they were in a considerable proportion of cases of lopsided distribution, being much more advanced in one lung than in the other. Of 230 cases 43 showed gross asymmetry; 30 had recognisable tuberculosis; 3 others were of special interest. One had a smooth-lined (? healed tuberculous) cavity with a surrounding shell of black rubbery fibrosis and no naked-eye fibrosis elsewhere in either lung. Another exhibited a similar condition, but with more marked fibrosis in, and a calcified gland at the root of, the right lung, and on the left side scanty nodular lesions with one larger lesion about 3/4 in. in diameter. The third, with an old healed empyema on one side, had an almost wholly consolidated black lung on that side, with relatively minor lesions in the other. In 10 other cases there were massive necrotic lesions on one side, with much smaller though often confluent lesions on the other. Asymmetry of lesser, but definite, degree was noted in 18 other cases.

Infection, whether past and obsolescent, or present and active, whether tuberculous or non-tuberculous, appears to be the most likely factor responsible for the lopsi distribution of the fibrotic masses.

Silica is an adjuvant to tuberculosis, coal dust credited with an inhibitory effect (Cummins and Weatherall 1933), and the interplay of these two effects is probably responsible for much of the modification of tuberculosis in silicotic coalminers.

Emphysema.—Minor degrees of emphysema are readily detected at necropsy in the blackened lungs coalminers, but dilation of air spaces was often perc tible, and gross bullous emphysema was common, bei noted in 104 of 230 cases. These were men with sev disablement and massive lesions, except some of old men certified partially disabled by silicosis a usually dying of extrapulmonary diseases.

Pneumothorax due to rupture of an emphysemato bulla may occur, and one man died shortly after develo ing a total pneumothorax on the side of his bet lung. It is possible that this happens more commor than we know but is often partial owing to adhesio I recall one man who had three attacks of pneumothora which, owing to limitation by pleural adhesions, present a puzzling clinical picture.

Non-tuberculous Respiratory Affections.—These we found in about a fifth of the cases. The condition mo commonly found was bronchopneumonia. Lobar pne monia was uncommon, being present in only 2 case Gardner has remarked on this fact. If pneum coniosis involves extensive portions of the lungs it w impair the chance of recovery from any pneumonia reducing the available reserve of functioning lung tissu but apparently it does not render the patient particular liable to lobar pneumonia.

Cardiac Changes.—Opinion is divided about the effe of pneumoconiosis on the heart, and South Africa observers (Irvine, Simson, and Strachan 1930) rema that congestive cardiac failure as a mode of death less common in the recent South African cases than ha been reported in the old miners who had been expose to very heavy dust concentration.

In the present series of 230 cases heart-failure wa the most frequent mode of death. Two types of failur were noted in about equal proportions: (1) congesti cardiac failure, with dropsical limbs, ascites, &c., an (2) terminal failure of circulation, with pulmonar œdema and congestion. These men rapidly develope increasing dyspnœa and tachycardia, dying not suddenl but in a few days.

In 84 cases terminating in one of these ways hypertroph and dilation of the right heart, with chronic venous con gestion of the liver and other viscera, were practically constan In only 4 cases were massive confluent lesions lacking, an these exhibited other cardiac abnormalities.

Of 41 cases of non-tuberculous respiratory affections 2 exhibited right-heart changes and chronic venous congestio of the liver and other viscera All of these had massiv confluent fibrosis.

Of 59 cases recognised as tuberculous at necropsy 29 showe right-heart changes. These all had massive lesions in th lungs, and 10 of the 29 presented a full picture of congesti cardiac failure, which appeared to be the mode of death.

These findings indicate that cardiac embarrassment i a common sequel or concomitant of coalminers' pneumo coniosis, especially in men with massive lesions. This i only what one might expect in view of the extensiv destruction of the pulmonary capillary bed, furthe augmented, as it usually is, by emphysema. Simila cardiac effects in miners in the Ruhr are referred to by Böhme (1939), di Biasi (1939), and Schulte and Husten (1936), and in America by Coggin et al. (1938)

Carcinoma of the Lung.—Recently the question has been raised whether there is in silicotics an increased susceptibility to lung cancer. This question has cropped up before in connexion with the increased incidence of lung cancer in *Joachimstal* and Schneeberg miners, but such a highly nocuous material and it will probably cease to be a menace to health long before we reach anything like total suppression. I believe that the sheer bulk of the inspired dust is important, and that, once dust suppression reaches a stage at which a balance between intake and elimination is approached, much of the dust disease will disappear, as the self-cleansing mechanism of the respiratory system will not then be overwhelmed.

I do not consider that aluminium, introduced experimentally in Ontario, is likely to be of any use as a protective agent against the mixed dust encountered by coalminers.

Another preventive step which will probably be taken before long is the medical examination of workmen before employment and periodically afterwards. This I consider important because I believe that in many cases the seed is sown, or the soil for the silicotic crop prepared, before the boy reaches the mine. Here I enter a strong plea for the exclusion of the man with tuberculosis from the mine. It is probable that the presence of a man with open tuberculosis in the heading is part of the explanation of the deaths of whole teams of "hard headers" such as have been reported in the past. Yet no person or authority has the power to keep the miner with tuberculosis out of the pit.

TABLE V.—AGE-DISTRIBUTION AND NECROPSY FINDINGS IN 592 DEATHS AMONG CERTIFIED SILICOTICS

Cause of death	Age at date of certification (years)				Total
	Under 40	40–49	50–59	60 +	
Silicosis (or pneumoconiosis) plus tuberculosis	29 (*20·0%*)	48 (*33·1%*)	42 (*28·9%*)	26 (*17·9%*)	145
Other silicotic deaths	23 (*6·1%*)	95 (*25·6%*)	169 (*45·5%*)	84 (*22·6%*)	371
Non-silicotic deaths	2 (*2·6%*)	11 (*14·4%*)	29 (*38·1%*)	34 (*44·7%*)	76

TREATMENT

There are no special therapeutic resources at present available, apart from treatment of complicating infections. It is hoped that the unit at Cardiff for research into the possibilities of treatment and rehabilitation of pneumoconiotic miners in charge of Dr C. M. Fletcher may evolve something useful. It may be possible to get men back to a useful condition by some form of training.

SOCIAL ASPECTS

These are most important considerations. The amendment of legislation in 1943 has led to the suspension of many mine-workers at a comparatively early age. This has created a grave man-power problem. The answer is to rid the mines of dust, but the transition problem remains, for the disease is of slow development.

There is also the social problem of providing for the men suspended. A large proportion of these, especially men suspended in the last two or three years, have little, and sometimes no, disability. Many, even advanced silicotics, have helped to man war factories. Most of the suspended men can do ordinary factory jobs. Provision is being made for them by the introduction of new industries to the coalfields. For the men with more severe disablement it may be possible to provide some more "sheltered" occupation, but it is hoped their numbers will be fewer before very long.

SOME UNSOLVED PROBLEMS

We do not yet know why there is a higher incidence in anthracite than in steam and bituminous mines, though King (1945) has hinted that steam and bituminous coals, perhaps by reason of a more intimate mixture with their contained mineral matter, may prevent their contained silica from acting on the tissues with which it comes into contact.

Another unanswered question is that of varying individual liability to dust disease. That men vary in their susceptibility to the effects of dust is certain. I shall cite only two instances.

One man worked for thirty-five years in hard headings: all his working life he spent in them. Five years before his death he was a robust man with a chest expansion of 5 in. Less than a year before his death he began to fail, and within a few months of ceasing work he died with a classical silicosis, like that of the stone-mason, and a galloping tuberculosis.

Another man died at the age of 65 after fifty-one years of underground work: about four years in hard headings and the rest at the coal-face. He worked in a mine with a very high incidence of the disease, but at death his lungs were little different from those of the ordinary town-dweller.

At the other extreme, men have developed dust disease after only a few years in the mine, but in these tuberculosis has been a prominent factor. There must be personal factors at work to explain this variation in susceptibility to dust disease. Doubtless infection is one factor.

Many facets of the problem of coalminers' pneumoconiosis have been passed over. No explanation for them can be offered at present, and the whole problem is so tangled that a full solution will require many years of work in many fields. We are dealing with a mixed dust of which one ingredient, silica, especially in the form of quartz, is an adjuvant, though not always a whole-hearted one, to tuberculosis; another, coal, is credited with an inhibitory effect on tuberculosis and, either alone or in combination with other ingredients, an antidotal effect on the silica. The addition to these mineral factors of the living variables, the man, the tubercle bacillus, and perhaps other organisms, produces a very complicated polygon of forces, and it is not surprising that the disease presents such an intricate tangle.

SUMMARY

The clinical features and morbid anatomy of pneumoconiosis in anthracite miners are described, and associated conditions are discussed with special reference to tuberculosis.

Associated tuberculosis was present in 24·5% of 592 certified miners who died, and in 28% of 516 silicotic deaths. Tuberculosis accompanying pneumoconiosis in coalminers is often lacking in its usual features, both clinically and post mortem, and it is certain that more detailed investigation would reveal tuberculosis in a much greater proportion of silicotic miners who die of their disease.

Gross emphysema was another common accompaniment of the advanced stage of the disease, and emphysema is responsible for much of the disablement in these men.

The predominant modes of death have been indicated. A considerable proportion of certified men died of intercurrent and unrelated diseases, as would be expected when so many of them are old men. Of the "silicotic deaths" about half were due to cardiac failure and half to infection, tuberculosis being found rather more often than non-tuberculous affections.

Signs of embarrassment of the right heart were often found in the men with more advanced pulmonary lesions, even apart from the patients dying of cardiac failure.

This series of cases offers no evidence that there is any increased incidence of primary lung cancer in pneumoconiotic anthracite miners.

The mortality among men in the different categories of certification has been compared. Men with clinically recognisable tuberculosis have a particularly poor prognosis, but many with advanced disease and most of those certified in the early stage survive for many years.

men who die and not to the far greater number who have survived, and will survive, often to a ripe old age, then to die a "natural" death.

The figure for "total" cases in table IV includes all cases of total disablement, whether certified simply as silicosis or as silicosis plus tuberculosis; but the error introduced by this is not great, as the proportion of men recognised to be tuberculous at certification is small. The average age of certification for all cases of total disablement in this table is 52, as compared with 53 in table II, where the two categories are given separately.

TABLE III—ANALYSIS OF 592 DEATHS AMONG SILICOTICS

—	Tuberculosis	Other silicotic deaths	Non-silicotic deaths
All deaths (592) ..	145 (*24·5%*)	371 (*62·7%*)	76 (*12·8%*)
Silicotic deaths (516)	145 (*28·1%*)	371 (*71·9%*)	..

The average survival period for 370 "total" cases in table II is $4^{3}/_{12}$ years.

The relative mortality among men certified totally and those certified partially disabled is very clearly indicated by comparing tables II and IV. From these it is seen that, whereas "partial" certificates comprise over 76% of those issued during life, deaths among "partial" cases amount to less than 20% of the deaths, and a third of these were due to causes unrelated to silicosis. In contrast to this, certificates of total disablement were less than 24% of those issued during life, whereas deaths among "total" cases (simple or complicated by tuberculosis) amount to over 80% of deaths, and of these only 10% were non-silicotic deaths.

The figure for tuberculous cases in table II refers only to men recognised as such when certified, and underrates the incidence of tuberculosis in silicotic miners. This is shown in table III, where it is seen that tuberculosis accompanied silicosis in 24·5% of all 592 deaths and in 28·1% of 516 "silicotic" deaths.

For men certified as silicosis plus tuberculosis the average age at certification is somewhat lower than for other cases of total disablement: $48^{7}/_{12}$ as against 53 (see table II). The survival period of this group is much lower than for the other groups, both "total" and "partial," averaging only $1^{10}/_{12}$ years for 53 cases. The prognosis for this group is very bad, although some men may carry on for a long time, the longest period in this series being $6^{4}/_{12}$ years.

It is only men recognised as tuberculous at certification for whom the prognosis is so poor. The men not so recognised fare better. One man, certified simple silicosis, whose lungs revealed at autopsy silicosis plus tuberculosis, lived 14 years after certification. For the men in my personal series the survival periods of cases grouped according to the three main necropsy findings were as follows:

Cardiac failure	$4^{9}/_{12}$
Non-tuberculous respiratory affections ..	$3^{7}/_{12}$
Tuberculosis	$3^{10}/_{12}$

If cases recognised as tuberculous when certified are excluded, the last figure becomes $4^{9}/_{12}$.

All the figures so far mentioned afford only a partial guide to prognosis. In an effort to obtain a better guide a follow-up of all men certified in 1935 and 1936 was made.

Of 158 men certified totally disabled by silicosis in an advanced stage 100 were alive at the end of five years; of the 58 deaths, 47 were due to silicosis, 8 to natural causes, and 3 to causes unknown. Of these 158 men 57 survived into the tenth year, 81 having died of silicosis, 10 of natural causes, and 10 of causes unknown. A fairly high proportion even of the old men have survived for long periods, nearly a third (7 out of 24) of the men over 60 at date of certification having survived into the tenth year, among them one old stalwart of 68 who is still alive after ten years.

Of 53 men suspended in the early stage of the disease only 3 were dead by the end of five years: 1 dying of silicosis, 1 of natural causes, and 1 of causes unknown. Of this group 44 survived into the tenth year, the 9 deceased including the 3 men mentioned above and 6 others who died of causes unknown.

A small group of men were certified with "partial disablement by silicosis moderately advanced," and these show an expectation falling between that of the advanced and e groups. Of 16 men in this group 11 survived five years, 8 into the tenth year.

In sharp contrast to the above groups, men recogni as tuberculous at certification present a much sad tale. Of 17 men certified suffering from silicosis p tuberculosis, 9 were dead at the end of a year, 14 w dead at the end of two years, and only 1 survived f years, living just into the fifth year.

Another feature of tuberculosis cases is a tenden to earlier onset of disablement in men with associat tuberculosis, whether recognised in life or at death on This is shown in table V, which gives the age-distributi in decades of 592 fatal cases, the age given being that date of certification or cessation of work, for the th groups, based on necropsy findings, silicosis plus tub culosis, other "silicotic" deaths, and non-silico deaths. Of the tuberculous cases, over a half occur the two younger age periods (30–50) and over a fifth the youngest (30–40).

Of the other "silicotic deaths" less than a thi occupy the two younger periods, and only slightly ov a twentieth occur in the youngest period, the large percentage falling in the sixth decade.

Of the non-silicotic deaths even smaller proportio occupy the two younger periods, and the highest pe centage is in the oldest age period (60+).

PREVENTION

This aspect of the subject can be dealt with on very briefly. In our anthracite mines we have not wait for the solution of the chemical, physical, and biologic aspects of the problem to develop preventive method Our Silicosis Research Committee have studied the loc features of the problem and have attempted to devel practical preventive measures. Briefly, we depend wind and water: water to prevent the liberation of du by infiltrating the coal seam before it is worked, spray dry coal and rock, to water roadways, and permit the use of wet drilling; wind in the form of a ample ventilating current to dilute and remove su fine dust as escapes the water traps. This fine dust, on liberated into the atmosphere, must, we say, be treat as a gas.

The limited problem of dust suppression in hard hea ings is not difficult of solution. Wet drilling, sprayi of broken rock, precautionary measures with shot-firin and an ample ventilating current will achieve success the only insuperable obstacle being the human on notably the man who will not use the protective apparat supplied. We now consider hard headings the safe places in our mines. It is a much more difficult matt to suppress dust at the coal face, and total suppressio cannot be achieved, but we are reducing the amoun The dust inhaled by the average coal-face worker is n

TABLE IV—AGE-DISTRIBUTION AND AVERAGE AGE OF CERTIF CATION OF DIFFERENT CATEGORIES IN 3745 CERTIFICATI (SILICOSIS OR PNEUMOCONIOSIS)

Category of certificate	Age at date of certification (years)				Total	Ave age certi catio (yea
	Under 40	40–49	50–50	60 +		
Totally disabled—silicosis (or pneumoconiosis) or silicosis plus tuberculosis	98 (*11·3%*)	238 (*27·5%*)	338 (*39·1%*)	190 (*22·0%*)	864 (*23·6%*)*	52

ig. 3—Wave-form of current passed through patient with the new apparatus: (a) monophasic; (b) diphasic.

echnical difficulties by producing a unit which would nduce a convulsion by condenser discharge.

There are two ways in which a condenser may be discharged: monophasically (unidirectionally) and diphasically (bidirectionally). Several workers have indicated that different results might be expected from these two types of current. The diphasic wave-form produces more intracellular disturbance than does the monophasic. We therefore decided to construct an apparatus capable of delivering monophasic or diphasic current from condenser discharge, *rather than to incorporate this feature in our universal argotron set.*

Before we discuss the theoretical and experimentally tested advantages of steep-wave *decremental discharge* in electroplexy and the apparatus used, it is desirable to give a short account of the MacPhail-Strauss first universal electroplexy unit, if only because, so far as we know, it is the only apparatus of its kind in the world. Moreover, it illustrates the considerable number of electrotechnical problems which have to be satisfactorily solved, before it can be considered safe to produce a piece of electromedical apparatus of this kind, destined to be used, for the most part, by people with little knowledge of physics.

FUNDAMENTAL CIRCUIT OF UNIT

The fundamental circuit of the argotron electroplexy unit is illustrated in fig. 4.

The transformer T1, T2, T3, T4, T5 may be excited through switches 9 and 12 by A.C. or D.C. mains, through the vibrator (6) and switches 8, 9, and 11, or from 12-volt supply from B through the same switches.

T2 supplies a small A.C. voltage through R3 across R4. This permits a known A.C. current (125 microamps) to flow through the shorted jack, when the calibrated resistance is maximal (1000 ohms). The introduction of the patient's impedance causes a drop in the current flowing. By decreasing R5 till the same current-reading at the reference line is shown (125 microamps), the subtractively calibrated scale of R5 will indicate the patient's impedance directly.

T3 and T4 provide a source of direct current through rectifier V1, which charges timing condenser C3. On throwing the switch TS, the charge excites the relay R, which will momentarily close switches S1, S2, S3, and S4. Calibrated control R6 gives exact timing plus or minus $^{1}/_{100}$ sec. from $^{1}/_{10}$ to 1 sec. in steps of $^{1}/_{10}$ sec. R7 is the minimal timing limiter.

The patient's shock transformer, T6, T7, T8, may be excited from A.C. via centre tap of T6 and switch 14. It may be excited from D.C. via 13 and 14 and argotrons A1 and A2. The "flywheel" of the circuit is C1 and choke 15. Grid-control and phasing is from T4 and R1; and R2, C2 provide bias.

The shock transformer may also be excited from a 12-volt battery through vibrator 7 and T7.

T8, the shock winding, is rated at 200 watts and provides shock-voltage from 35 to 145 volts in 5-volt steps. N2 is a neon pilot showing moment of shock. J2 is patient's shock jackhole.

N1 is the neon showing when the set is "*on*."
4 is the battery circuit fuse.
3 is the A.C./D.C. mains fuse.
17 is the patient's circuit fuse.
5 is the battery-supply switch.
2 is the mains-supply switch.
1 is the vibrator dropping resistor for D.C. mains.

ADVANTAGES OF STEEP-WAVE CURRENT

All of the advantages which we anticipated might belong to steep-wave, as opposed to sinusoidal, currents were shown to exist when the method was tried out in practice:

(1) The steep-wave current has a much higher equivalent frequency and a higher potential gradient. From this we deduced *(a)* that we might be able to dispense with the preparation of the skin, because even a very greasy and sebaceous integument could be calculated to offer *but little* resistance to this type of current; and *(b)* that we might be able to reduce the area of electrode surface, so as to deliver the current transfrontally in the form

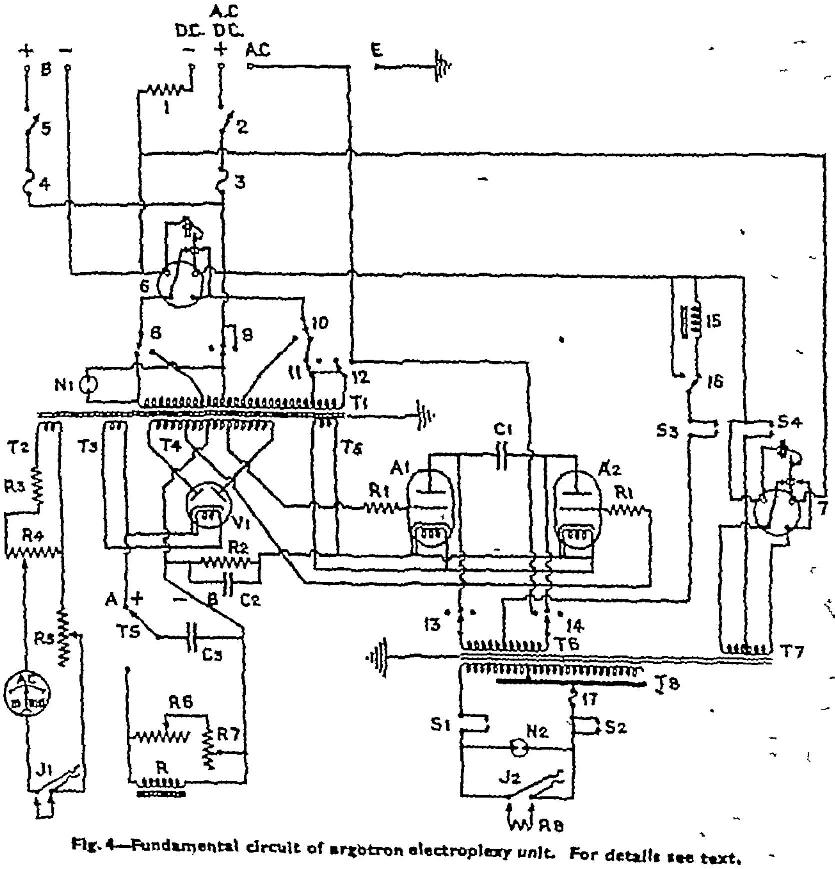

Fig. 4—Fundamental circuit of argotron electroplexy unit. For details see text.

There is a tendency to earlier onset of disablement in men showing evidence of associated tuberculosis in life or at death than in the apparently uncomplicated cases.

Prevention and social and other aspects of pneumoconiosis are briefly referred to.

STEEP-WAVE ELECTROPLEXY

E B STRAUSS
M.A., D.M. Oxfd, F.R.C.P.
PHYSICIAN FOR PSYCHOLOGICAL MEDICINE, ST. BARTHOLOMEW'S HOSPITAL, LONDON; HON. RESEARCH PSYCHIATRIST, MAIDA VALE HOSPITAL FOR NERVOUS DISEASES

ANGUS MACPHAIL
F.I.E., M.S.R., C.S.P.
RESEARCH ELECTROPHYSIOLOGIST, MAIDA VALE HOSPITAL FOR NERVOUS DISEASES

THE object of the steep-wave type of electroplexy or electric convulsion therapy (E.C.T.) is to produce therapeutic convulsions with minimal discomfort to the patient, minimal damage to nervous tissues, minimal disagreeable after-effects, and minimal risk of extraneous accidents.

Though from the purely technical point of view much progress has been made in the design and construction of electroconvulsant apparatus—and we ourselves, year by year, have attempted to improve on our own work—it cannot be claimed that there has been any progress involving *principle* since Bini and Cerletti constructed their first apparatus.

Up to now, all apparatus, good, bad, and indifferent (and there have been some which have been open to serious electrotechnical criticism), have been constructed to deliver an alternating current (A.C.) at a selected voltage over a selected time-interval. In other words, a fit was to be produced by bombarding the cerebral cortex over a relatively wide area with a sequence of A.C. electrical impulses of (theoretically) equal voltage, during the passage of which the transtemporal resistance had been considerably reduced by the first few impulses. The wave-form, on analysis, in all types of A.C.-excited apparatus is approximately sinusoidal.

The noxious effect of this sinusoidal type of current on cortical neurones is still controversial, though the latest work shows that it can be reduced to a negligible factor by proper precautions. Nevertheless, that structural changes do occur, even though they are not necessarily irreversible, is shown by the organic type memory-defect and by the recorded changes in th electroencephalogram which are commonly associate with electroplexy.

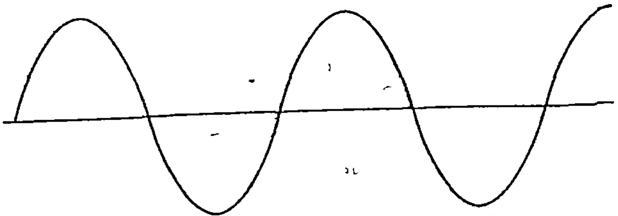

Fig. 1—Wave-form produced by first standard A.C. mains unit.

It therefore occurred to us some five or six years ag that it would be desirable to induce fits electrically wi a type of current (thinking in terms of wave-form) whic would be calculated to effect as little structural intr cellular or extracellular change as possible. Experienc of other forms of medical electricity has shown tha as a general rule, with the steeper wave-forms not onl is structure less affected but excessive physiologic excitation is avoided (Krusen 1941, MacPhail 1936).

FIRST EXPERIMENT

Electrotechnically, we have found that the simples way of administering a steep-wave current is wit condenser discharge. Accordingly, very early in ou researches we tried to adapt this principle to clinica electroplexy. Our first experiment was unsuccessfu because we did not see our way immediately to overcom the technical difficulties. We should doubtless hav been more persevering, had we not been so agreeabl preoccupied with the clinical successes that we wer piling up with our first portable A.C. apparatus (Straus and MacPhail 1940).

However, when we decided to construct a univers unit—i.e., a unit which could be used on A.C. or direc current (D.C.) mains supply or with a 12-volt battery—we decided that, on electrophysiological grounds alon we ought to try and steepen the wave-form. Fig. 1 i an actual recording of the wave-form produced by ou first standard A.C. mains unit. It is strongly sinusoida and it shows uniform amplitude in both positive an negative phases. Fig. 2 is a recording of the wav produced by our first standard universal unit (*a*) fron D.C. mains, generated by argotrons, and (*b*) from a 12-volt battery supply, generated by vibrators. The argotron-generated current has a much steeper leading front than the normal alternating current, and also has a high frequency spike of fair amplitude in both phases. Th vibrator-generated current has a vertical leading front though the rapid spike-decrement opens out to a lower frequency component. Though the wave-form has bee steepened, the energy factor remains uniform for eac impulse, as shown by the absence of train-decrement.

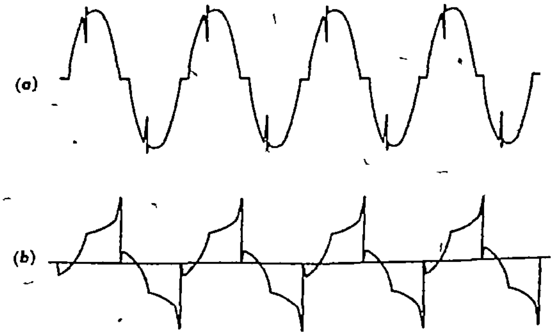

Fig. 2—Wave-form produced by first standard universal unit: (*a*) fron D.C. mains, generated by argotrons; (*b*) from 12-volt battery supply generated by vibrators.

A rapid change in inter-electrode resistance during th first few impulses of the shock current indicates th advisability of using a rapidly damped train of waves. The higher voltages at the beginning overcome the initial resistance, and the subsequent train-decrement ensures that minimal energy is used to induce the fit. In other words, the first few high-voltage impulses initiate the fit, and the subsequent impulses, which taper off rapidly, complete the electrophysiological action. We therefore decided to go back on our tracks and try to overcome the scale, in the centre is the joule-meter registering the dose, and on the right can be seen the shock charge control.

Fig. 7 shows the headgear, which consists of a tempered 'Perspex' band, at the extremities of which are two stainless-steel electrodes, $1^{1}/_{2}$ in. in diameter, having a ball-and-socket mounting. Each electrode-mounting has a plug-hole, $^{1}/_{8}$ in. in diameter, which will take a standard wander-plug of stainless steel.

The use of stainless steel throughout prevents saline attack.

TECHNIQUE

The technique is substantially the same as with previous equipment as regards the general management of the patient and the precautions, but there is considerable simplification in the matter of electrode application and dosage.

The lint pads are well soaked with 20% saline and are sprung on to the temples, where they are self-retaining.

The position of the electrodes should be such that the lower edge is tangential to a line drawn from the outer canthus to the superior attachment of the pinna, at a point at the junction of the anterior and middle thirds of that line. No scrubbing-up or preparation of the skin are necessary.

Since resistance plays a negligible part in the estimation of dosage, it will be found that all patients have a satisfactory major convulsion with 20 joules diphasic or 25 joules monophasic current.

Monophasic current appears to produce slightly less confusion and makes for a quieter recovery. Diphasic current, because of its large peak-to-peak swing, guarantees a major reaction in subjects who are agitated and very restless, and when it might be difficult in consequence to get good electrode contact. In such cases diphasic current will overcome poor contact difficulties.

CLINICAL OBSERVATION

The indications for steep-wave electroplexy differ in no way from those for other types of E.C.T., and the clinical results appear to be identical.

Up to date, we have formed the impression that (1) the convulsions are less violent and sooner over; (2) recovery from the fit is more tranquil and more rapid; (3) the dispensing with scrubbing-up much shortens the whole procedure, so the patient is spared many anxious moments and receives the shock in a more relaxed state of mind and body, which, we are convinced, reduces the liability to muscle-strain and fractures; and (4) the time taken between the patient's mounting the couch and receiving the shock is, with our present type of apparatus and headgear, only a second or two—a great advantage in an agitated or hesitant patient.

SUMMARY

Our previous work on electroplexy has been briefly surveyed to indicate the factors which led us to construct a new type of apparatus.

A method of inducing electrical convulsions by a steep-wave current with a rapid decrement is described.

The technical and electrophysiological advantages of steep-wave current derived from condenser discharge are assessed against the effects of currents with other wave-forms of lower frequencies (including simple alternating currents).

The construction of the apparatus and its use are described in detail.

The clinical advantages to be expected from steep-wave electroplexy are outlined.

PSYCHOTHERAPY OF ULCERATIVE COLITIS

RANYARD WEST
M.D. Lond., D.Phil. Oxfd, M.R.C.P., D.P.H.
EDINBURGH

To call a morbid condition psychogenic or psychosomatic is to recognise that emotions play a large part in its causation. Therefore it is natural to hope that emotions can play a large part in its cure. Sometimes such hopes are realised: too often they are not. A disquieting feature of the psychotherapy of many psychosomatic disorders is a tendency to relapse.

It is important to remember that all psychotherapy works by altering emotions. Emotions are very labile: they are much more easily changed than are most organic states. Often they can be radically altered for a time. But, unless we can introduce a profound new understanding of himself to our patient, or tap an unfailing source of new confidence within his own mind, any temporary relief of anxiety which our self-confident explanations may produce is unlikely to cause more than transitory relief of any complex psychosomatic disorder. The old emotions become reinstated. And a physical disorder may be awaiting their return. Such, for instance, is a case of duodenal ulcer with remissions of duodenal spasm.

How far must one go in psychotherapy? What must one attempt to do? The following cases are recorded because, in demonstrating a real but very precarious psychotherapeutic success in warding off a dangerous organic malady, they offer an opportunity of reviewing our methods of approach to the psychogenic factor in physical illness.

CASE-RECORDS

CASE 1.—A trade representative, aged 36, was admitted to the Royal Infirmary, Edinburgh, on Oct. 30, 1944, complaining of the passage of frequent bloodstained stools. For three months he had passed 6–10 motions daily. He had also had abdominal discomfort and distension, and at the onset of the attack he had vomited five times.

He had had three previous milder attacks. The first was in 1940 just before he was discharged from the R.A.F. with a diagnosis of fibrosis of the lung. It had lasted seventeen days. The second was in March, 1944, and the third in July, 1944. The second attack had lasted on and off for three months, with stool frequency of 6–8 a day, reduced by medicines to 3 or 4 a day.

On admission the patient was very thin and anxious-looking, hollow-eyed, and hollow-cheeked. He looked ill and dehydrated. Muscles poor in tone. Abdomen distended and hypotonic. No abdominal rigidity. Tenderness along cæcum, ascending colon, and descending colon. Per rectum he was very tender, with a very tight anal sphincter and a narrow contracted rectum. The stool contained frank blood, epithelial cells, and pus cells, but no cysts, ova, or abnormal organisms. A barium enema was not given until Nov. 28, when it showed a spastic smooth-walled colon with loss of haustration, and some dilatation of the terminal ileum. Ulcerative colitis was diagnosed.

At first the patient was treated with a low-residue diet, ascorbic acid 150 mg. daily, ferrous sulphate gr. 3, and mist. catechu $^{1}/_{2}$ oz. four times daily, and phenobarbitone or 'Soneryl' at night. He did not improve. On Nov. 4 his weight was 7 st. 6 oz., on the 11th 7 st. 1 lb., 14th 7 st. 6 lb., 18th 7 st. 2 lb. His motions, though less frequent than before admission, were never less than three a day from Oct. 31 to Nov. 14. They continued to be fluid stools containing blood and mucus. Patient continued to eat poorly and to worry over every detail of diet and treatment.

Psychological Investigation.—The patient had vouchsafed on admission that he thought his first and second attacks had been connected with the onset of air-raids in 1940 and the flying bombs of 1944. Thirteen days after admission, on Nov. 11, a fuller history was taken of the relationship of emotion to his attacks of diarrhœa. This showed that his first attack of severe diarrhœa had developed in a military

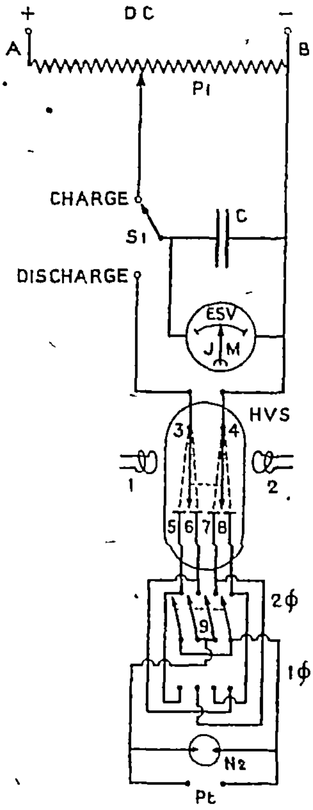

Fig. 5—Fundamental circuit of condenser-discharge E.C.T. unit. For details see text.

of a narrow beam rather than in the diffusely irradiating manner occurring with the much larger A.C. electrode plates.

(2) Seeing that the initiation of a convulsion depends on the impedance-breakdown effect of the first few impulses, it is desirable that the later impulses should show a rapid decrement or damping, so as to minimise subsequent cortical neuronic bombardment, while at the same time ensuring the induction of a major fit.

Fig. 3*a* is the record of the current through the patient, delivered by our new apparatus (monophasic). It will be seen to be a steep box-wave, highly damped, which is, we believe, the most innocuous form of high-energy current to which the central nervous system can be submitted for this purpose. Fig. 3*b* shows the same current produced diphasically.

(3) This is a consideration which arises as much out of the use of condensers as from the actual form of the wave, but which is none the less relevant in this context. It has always seemed to us undesirable and electrically "untidy" in computing dosage to have to reckon in terms of time and voltage and even of current. It seemed to us much more scientific and clinically more foolproof if we could reckon dosage in terms of total energy. A steep-wave current delivered by a rapidly discharging condenser provides the ideal form of electrical discharge to be measured in that way. For obvious reasons, the time-factor does not enter into it, since impedance, on the one hand, and capacity and total discharge of the condenser, on the other hand, determine the natural decrement. We therefore decided to calibrate our shocks in joules rather than in volts.

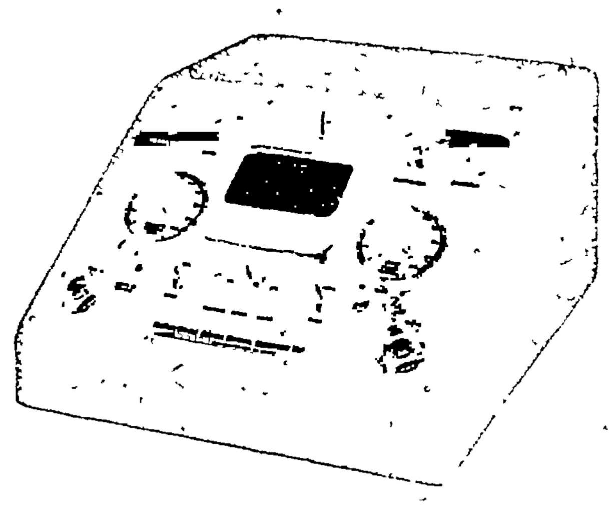

Fig. 6—Universal electroplexy unit with carrier cover removed.

(4) It sometimes happens (very rarely we must admit), when using our earlier types of apparatus, that a patient is found to be almost unconvulsible, even at high voltage and with a long time-base (up to $^1/_2$ sec. and up to 130 volts). It is to be presumed that shocks of this brutal kind (and often three or four are given in succession), even when they do not produce the desired convulsion, are to be avoided as approaching the threshold of damage to nervous tissue. We therefore wished to produce an apparatus which would be calculated to convulse any patient with the first shock.

If the dosage with our new apparatus were calculate in terms of volts instead of joules, the figure woul impress the physiologically uninstructed as being ver high. For example, 15 joules on our new scale corresponds to 300 volts. But it is important from the star to realise that this figure applies to the first impuls only. In point of fact the human brain can stand th transit of momentary peak-voltages in excess of 200 volts without sustaining damage.

Since it is the first impulse or so which initiates th convulsion, with our new type of apparatus we can b

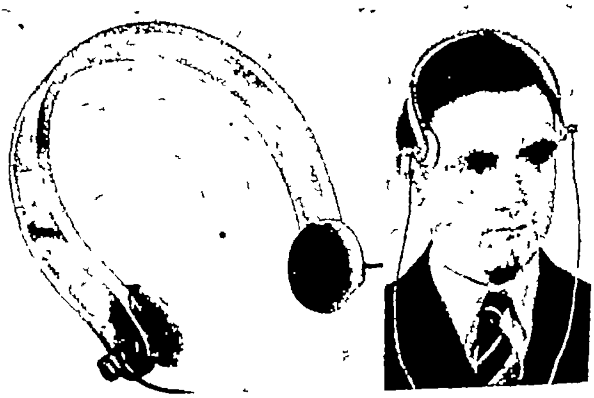

Fig. 7—Headgear.

sure of convulsing a patient with a high-peak first impulse, which we can deliver surely, safely, and conveniently.

DESCRIPTION OF APPARATUS

Circuit.—The circuit, like that of the universal argotron E.C.T. unit, will operate on either A.C. or D.C. mains 200/250 volts or from a 12-volt battery. The circuit is a combination of fig. 4 and fig. 5; from the mains output to the high voltage D.C. source A, B, the circuit is identical with fig. 4. T5 and all the circuit to the right is omitted, since this of course refers to the argotron convertor.

The D.C. source across A, B is applied across the potentiometer P1 (fig. 5). When the switch S1 is thrown to the charge position, the condenser C is charged to a voltage indicated on the electrostatic volt-meter calibrated in joules (JM).

To convulse the patient, the switch S1 is thrown to "discharge," and the charge from the condenser is transferred to the patient via the high-vacuum switch (H.V.S.) through the magnetically operated high-speed switch-points 3, 4 and the fixed switch-points 5, 6, 7, and 8. Switch 9 enables the discharge to occur either monophasically or diphasically. N2 is a neon indicator showing the passage of the discharge. Coils 1 and 2 are the exciting coils producing the high-speed oscillatory movement of 3 and 4.

Apparatus.—The apparatus is illustrated, with the carrier cover removed, in fig. 6. It is about 14 in. square and 7 in. high and weighs 25 lb. The cabinet work is of pressed aluminium finished in hospital cream enamel. On the left of the control panel is the patient's resistance bdominal sensation as dive-bombing had done later, and the ncertainty of his father's moods had been a very important actor in his childhood.

Character Type.—Slight, nervous, and readily truculent. Very short in stature, with a limp dating from childhood. A strong feeling of inferiority ("everybody is before me"), apprehension of violence for which he always felt he must be prepared and with which he was determined to cope. Careful in dress, meticulous in habits. He had become a skilful cook with a very inadequate apprenticeship. Dependent on his wife, but inclined to domineer over her.

On admission: no wasting; pale pasty complexion; abdominal tenderness in cæcal region; frequent passage of fluid stools containing blood, pus, and mucus, but no abnormal organisms.

Barium enema: loss of haustrations and variable spasm of colon. Immediately after the patient was startled by a sudden noise the barium was seen to be shot far into the small bowel.

Sigmoidoscopy: pain and spasm; mucosa much inflamed, œdematous, and readily bleeding, with numerous small superficial ulcers.

Treatment: non-residue diet and mild palliative physical treatment only. Psychological treatment included about twenty hours of elucidation of his character type and the significance of fear and aggressiveness in relation to his bowel contraction, with full recognition by patient of the significance of his early childhood memories in this regard.

Progress: rapid. Urgent fluid stool only after drinking hot tea in the morning. Patient discharged in a month, with decision to give up "arguing"—i.e., offering fisticuffs—and to take a public-house business of his own. He remained well and at work for at least three months, with occasional diarrhœa under stress, but no blood or pus.

Case 3.—A married lady, aged 45, was admitted on Feb. 2, 1946. An only child, at the age of 15 she had lost her mother, to whom she had been devoted. Her father had married again when she was 16, and she had "never forgiven him" for that. *For ten years she had suffered* under the violent temper of her stepmother, who had later been admitted to an asylum. Her father, now aged 77, lived with her and her husband There were two children. Her father was alcoholic, a reprobate and a tyrant. ("I have to wait on him hand and foot.")

Her first attack of diarrhœa, in 1945, had been accompanied by the passage of "white skins" a few days after a New Year's Day celebration of her father's, during which she had found him covered with blood from a fall in the street.

A second attack had occurred in March, 1945. It had been attributed to tinned pork. Her son had had mild, and she severe, diarrhœa. But her father had just taken to bed for ten days, giving her "more work and worry" On March 20, 1945, a female cousin, to whom she had been greatly devoted, had died of phthisis. Thereafter her diarrhœa had become constant, 9 or 10 liquid stools per day and 1 at night, usually thin and brown, sometimes green, with "lumps of red" and frank blood.

Character Type.—Fastidious over food, house-cleanliness, and clothes; sensitive to criticism, tyranny, and tempers, finding her husband "difficult" and her father dirty and untidy. Inclined to get her own way through illness In childhood she had vomited every Saturday after her father had been ill-treating her mother. Readily hysterical. Probably much deep unconscious guilt.

On admission: pale thin anxious face with wide eyes and small mouth. Moderate general abdominal tenderness. Fluid stools containing no abnormal bacilli, cysts, or ova, but pus, blood, and mucus.

Barium enema: absence of haustration in sigmoid and descending colon; walls of ascending colon and sigmoid irregular; appearances those of colitis.

Sigmoidoscopy: œdematous congested mucosa, with extensive superficial ulceration and numerous bleeding points.

Treatment.—Penicillin 30,000 units 4-hourly for eighteen days, sulphathiazole, belladonna, ascorbic acid, 'Luminal.' Severe anæmia (Hb 48%) required two transfusions. Psychological treatment included about twenty hours of elucidation of patient's character type and its relation to the emotional experiences which brought on diarrhœa, all being fully explained to patient.

Progress.—Rapid cessation of bleeding and diarrhœa. Setbacks at all domestic *crises* which were reported to her, until her father was admitted to an almshouse and her husband's working conditions improved. Thence almost uninterrupted recovery. Sigmoidoscopy (March 25, 1946): much improved, but granular mucosa and one or two bleeding points. Thrombophlebitis of one leg followed second blood-transfusion.

Subsequent History.—No return of colitis, patient remaining constipated. Two months after admission, however, and when convalescence was nearly completed, patient passed rapidly into a psychotic state with profound guilt over her treatment of her father, and became demented and bedridden.

DISCUSSION

These cases illustrate characteristic features of ulcerative colitis and raise again the question of the mechanism of its development. The two most striking features of the cases are the prominence of psychogenic factors in causation, and the readiness of remission of symptoms.

Psychogenic Factors.—The connexion between the onset of the symptoms of ulcerative colitis and emotional disturbances, apparently little regarded in the earlier literature of the disease—e.g., Hurst (1921) and Hern (1931)—was fully recognised by Murray (1930), who also noted the frequency of fearfulness, emotional immaturity, strong maternal ties, difficulties over marriage, and emphasised the value of an "unburdening of repressions" in bringing about the intermissions which characterise the disease.

The tendency of patients with ulcerative colitis to be neat and fussy was noted by Sullivan (1935), who also emphasised that their high intelligence was often combined with an inability to throw off the effects of emotional episodes. This neatness and fussiness and the widespread inability to adjust the self to the demands of ordinary adult environment clearly place many cases of ulcerative colitis in the category of the obsessional character type. But Wittkower (1938), following up the conviction of Cullinan (1938) that in ulcerative colitis there were "emotional disturbances superimposed upon an unusual or abnormal personality," showed that among his 40 cases the character types were very diverse. They included 17 obsessionals and 12 hysterics; the obsessionals became ill through inadequate external events interacting with powerful internal conflicts, and in the hysterics the onset of diarrhœa was largely affected by dramatic external events. In Wittkower's series the second group was confined to women. Such diversity suggests that common psychological grounds for ulcerative colitis must be looked for at deep levels of primitive feeling or else in some common emotional drive at the time of the illness. There is psychoanalytical evidence that the tendency for emotion to become unduly linked with one particular bodily system or organ depends on psychological patterns laid down deep in character and early in life. One such pattern is that of Freud's anal type (Freud 1908, 1913), the more passive anxieties of which may possibly lead to a greater distortion of character in men than in women.

Remissions.—In ulcerative colitis there are abrupt but unstable responses to varied treatments (Hern 1931). Dramatic remissions, both of symptoms and of severe ulceration as seen by the sigmoidoscope, have followed the administration of antidysenteric serum (Hurst 1921, Maister 1928). Similar results have followed psychotherapy (Sullivan 1935).

In case 1 we do not know the actual state of the mucosa of the colon, since sigmoidoscopy was *not attempted*; but the contents of the stool and the radiological appearances after a barium enema suggested that severe ulceration was present. At the time of radiography the patient was in a phase of *acute relapse*, emotionally induced. He was passing much blood, mucus, and pus, and was about to lose 1 st. 8 lb. in five days. But during the ten previous days he had passed almost normal stools at normal frequency and had been rapidly gaining weight.

hospital, whither he had gone because of dyspnœa on exertion. At that time (1940) he had been oppressed by the comparative roughness of his military life and by his lack of promotion from the ranks. He had felt that he could have joined the Army as an officer, and he had looked for some recognition of the fact that he had chosen the harder way. Actually he had entered the R.A.F. as a volunteer in 1939, but opted for the Balloon Barrage because he "did not mind defence in war but could not bear to attack."

Immediately after this period in hospital with "bronchitis" and diarrhœa he had secured his discharge from the R.A.F. with a diagnosis of fibrosis of the lung and the comment that he should never have been in the Forces at all. He felt that he had collapsed on the very threshold of danger with the onset of the "blitz," and that his discharge on medical grounds was a thinly disguised defeat of his more courageous self. Yet, once out of the R.A.F., he had rapidly recovered his health.

In 1943 he had been in a civilian occupation which he had felt to be less cultural than the architectural metal work in which he had travelled before the war. He had become unable to deliver the goods to his customers owing to wartime restrictions. He had become "browned off" and worried that he was not really earning his money. So he had resigned his post voluntarily. Shortly afterwards, in March, 1944, there had been some dive-bombing near his home; his nerve had given way, and his diarrhœa had recurred acutely. By June he had recovered.

Next, in July, the flying bombs had come, and "Bang I went again," with gastric pain and diarrhœa, this time with the passage of blood. Not the least of his emotions then had been shame at his pusillanimity in the presence of his seven-year-old daughter, who had been anxious to block the air-vent of the family shelter with her body "to be sure of feeling the blast." By August he had improved again after obtaining a good job in Scotland, entailing security and a new house.

In September, 1944, immediately after seeing a war film, he had been strolling through the streets, brooding on the misery of the world and his inability to secure even himself against injustice, when a precipitating accident, very characteristic of neurotic illness, had happened. A sun-blind outside a shop slid down suddenly and hit him on the head. He had not been hurt, but deeply offended. He had reproached the shopman on the grounds that "it might have been a child that was hit." That same day he had relapsed into his latest and most severe attack of bloody diarrhœa.

The first diagnostic interview closed with an introductory explanation of the effects of emotion on bodily states, including the eliminative processes. Next day the stool frequency fell to two and the patient's weight began to increase.

Five days later (Nov. 16) a second psychological interview was directed to further elucidation of the patient's character type and his boyhood anxieties. His position in the family lay between two girls, with one much younger brother. He was extremely tidy in his habits—a statement borne out by his dapper appearance. His ideal had always been to help, to give way, and to forgive; to set an example and to prove that everybody could be won by kindness—an example which he felt that both his parents had in their turn set him. Sexual feelings had always been much repressed, but for years he had feared that he had caught venereal disease from a totally inadequate boyhood experience. Throughout his childhood, anxiety or injustice had always precipitated diarrhœa. He could not tell a lie.

Such accounts of himself were immediately related to the stresses he had been under in peace and war. This second interview aimed at explaining things to the patient. It contained a rough classification of character types, and a further account of the functions of the colon and its response to emotion. It occupied fully an hour.

Immediately after this interview the stools became normal in frequency (1 or 2 a day) and were usually partly formed. Signs of anxiety vanished. Patient ate well, his face filled out, and by Nov. 22 his weight was 8 st. 3 lb., an increase of 1 st. 1 lb. in twelve days.

On Nov. 28 a barium enema was given by a nurse, clumsily perhaps, but at least without warning to him and causing him pain, intense anal spasm, and renewed acute apprehension. Next day he vomited, and profuse diarrhœa recurred, with oliguria, thirst, and abdominal pain.

On Dec. 2, at a third interview, there was great resentment at the unsympathetic and painful rectal injection. The incident was used to confirm patient's anal sensitivity and his sensitivity to injustice and indignity were canvass more fully than before and related to this physical sensitivity For a few days patient had to be seen daily, each time for short revision of the findings.

The setback lasted a week and was most severe; hi weight fell to 6 st. $8^1/_2$ lb. (Dec. 3) and 6 st. 5 lb. (Dec. 9 But after the first two days he became confident that h would recover, and his recovery when it came was very rapid *This time he gained $1^1/_2$ st. in seven days.* He was discharged on a normal diet less roughage on Dec. 22, and hi weight, which had reached 7 st. $12^1/_2$ lb. before discharge rose rapidly to 9 st. early in the New Year.

For six months after his discharge he was on full work and he only occasionally had fluid stools, lasting twenty four hours and relieved by an opium and catechu mixture During these months he was "a little keyed up" from time to time and had one attack of acute anxiety while driving his car along a well-protected cliff road. Looking back, he now attributed his first attack of diarrhœa to "worry over the war, the state of the world, and the way things were going."

In subsequent months (to December, 1945) he had some return of diarrhœa on the following occasions: (1) on finding that his father, who lived alone, had become senile and was neglecting himself; (2) after rushing in to assist the victim of a motor-cycle accident; and (3) on hearing of the atomic bomb. On the last occasion he had to give up work for eight weeks, during which he could not keep his mind off the subject of Japanese atrocities. The relapse was attended with little loss of weight and no passage of blood. He returned to work nearly free of symptoms, though his stools were more often fluid than solid.

A follow-up for 1946 indicates that this patient suffered from temporary "spasms" and diarrhœa twenty minutes after a threatened road accident in February, while in April a severe relapse occurred immediately on hearing the noise of dive-bombing as a sound-accompaniment to a Mickey Mouse film—a sound which he associated with London air-raid panics and the feeling that "at best half of us may survive." About the same time he became troubled over the appropriate attitude for him to adopt to a new and domineering chief. Treatment by free association was now instituted at his home, but it failed. Despite the recovery of much semi-forgotten memories of the drunkenness and violence of a loved father and other early domestic anxieties, he continued to have diarrhœa, now with much abdominal distension and renewed loss of weight. He was admitted to another hospital, where his physical treatment was active and varied and included blood-transfusions, sulphathiazole, multiple vitamins, charcoal, kaolin, desiccated pigs' intestine, and sedatives. This was accompanied by the psychotherapy of being an interesting case in the eyes of distinguished physicians who demonstrated him as such to students. He slowly improved and was discharged home after two months. Here his convalescence became rapid after he gave up the anxieties of a job among strangers which was on a commission basis. Returning to the south of England he took up work again in the secure, familiar, more appreciative, and less competitive surroundings of his old pre-war firm (December, 1946). We can only speculate about 1947.

CASE 2.—A *chef de cuisine*, aged 34, married but without children, who had served as cook in the Merchant Navy and had been in good health until 1939, was admitted to the Royal Infirmary, Edinburgh, on Jan. 2, 1946, with ulcerative colitis.

The first onset of diarrhœa (thought to be dysenteric) had been in Montreal just before the outbreak of war. A subsequent attack had occurred in 1940 about the time of, but not coincident with, a bombing attack on his ship in the Manchester Canal. During the bombing "something had tightened up" inside him, and he thought this had led to the diarrhœa. In 1941 he had been twice torpedoed and once dive-bombed, but he had taken hold of himself and prevented it from "flying to his stomach." Since he had taken work ashore as a clerk in a shipping office, attacks had come on after dealing with quarrelsome crews. Attacks of sudden diarrhœa had also followed five minutes after drinking a cup of tea. Nowadays they were produced by any sudden noise, such as the back-fire of a car.

In childhood he had been devoted to his mother, and both proud and scared of his father, who had been kind and considerate when sober but violent when in liquor, especially to the mother. Violence from his father had given him the same

Such cases draw attention to the possibilities of psychological diagnosis and treatment in the early stages of ulcerative colitis in which colonic spasm is still (despite the presence of blood in the stools) the predominant feature.

They further serve as a reminder of the extent to which fundamental bodily machinery may be at the mercy of ideas, and of the high degree of reversibility which exists in psychosomatic illness when the psyche can be treated appropriately and in time.

Grateful acknowledgments are made to Prof. J. A. Ryle for much helpful suggestion and criticism, and to Dr. W. A. Alexander and Prof. D. Murray Lyon for permission to publish these cases.

FOLIC ACID IN TROPICAL SPRUE

REPORT OF A CASE

Sir PHILIP MANSON-BAHR
C.M.G., D.S.O., M.D. Camb., F.R.C.P.
SENIOR PHYSICIAN

OWEN CLARKE
M.B. Camb.
RESIDENT MEDICAL OFFICER

ALBERT DOCK HOSPITAL, LONDON

THE *treatment of tropical sprue has always been one* of the least satisfactory aspects of tropical medicine, and, despite intensive research in India and elsewhere during the war, no real improvement in treatment was achieved. This report describes the rapid and dramatic recovery of health when a long-standing and serious case of tropical sprue was treated with folic acid.

The patient left England for India in March, 1943, at the age of 27 years; he was category A1, and weighed 10 st. 8 lb. In February, 1944, he first noted that his stools were bulky, greasy, biscuit-coloured, and of unpleasant smell; but, except for purgative pills, he received no treatment before entering Burma for a three months' campaign with the Chindits.

"Inside" he was given three courses of sulphaguanidine, which stopped the diarrhœa but caused vomiting of similar foul-smelling matter, and between the courses the stools became larger and more sprue-like.

In August, 1944, when his weight was 6½ st., he was at last able to get proper treatment, consisting of controlled milk and orange diets, liver extract by mouth and injection, and nicotinic acid.

Neither this treatment nor return to the U.K. restored his previous health, though on his discharge from the Army a year later he could perform light duties The stools were too large and too greasy; he averaged two or three bowel movements daily, and any dietary excess was immediately punished. His weight varied from 8½ to 9 st. but never approached his previous normal.

A year in civil life has been similar to his last year in the Army; even light tasks have taxed his strength, and every moment of leisure has been spent in bed. Special diet, with extra meat, eggs, and milk, twice-weekly intramuscular liver injections, and nicotinic acid by mouth did not prevent the steady deterioration in his appetite and weight, and did not check his glossitis, breathlessness, anæmia, and diarrhœa with bulky, greasy stools. In September, 1946, he again sought hospital treatment.

On admission he was thin, pale, dehydrated, and very listless; *appetite* poor; weight at 7 st. 1 lb. was 3½ st. below normal; skin dry, desquamating, loose, and inelastic, even over a grossly distended abdomen; tongue smooth and sore, with marginal glossitis; typical sprue stools, passed three or four times in twenty-four hours, totalled 24 oz. daily. Blood-count showed megalocytic anæmia: red cells 2,430,000 per c.mm., Hb 50%. The gravity of his condition, especially the emaciation and dehydration, at first suggested that his life could only be saved by continuous drip blood-transfusion.

Treatment.—It was impossible to obtain folic acid for the first week of his treatment in hospital, during which time treatment differed little from his previous routine: controlled diets, predigested milk feeds; liver extract 'Plexan' 4 c.cm. given intramuscularly daily; nicotinic acid 100 mg. daily; and riboflavine 3 mg. daily. There was no pronounced improvement.

Folic Acid.—After a week the only medicine given was folic acid 10 mg. daily for five days by mouth. Liver extract and nicotinic acid were then resumed, and after ten days the plexan was reduced to 4 c.cm. on alternate days.

The effect of the folic acid was dramatic, and must compare with the recovery of the Cuban lady described by Spies et al.[1]

On the fourth day of the course of folic acid the patient said he felt fitter than for many months, his appetite became healthy, *and he was soon allowed full normal hospital diet.* Three days later the soreness of the tongue had ceased, though slight marginal redness persisted: the abdomen was not distended; and the skin had almost completely regained its normal elasticity. Most remarkable of all was the total absence of flatulence or of any abdominal discomfort. Within ten days he was taking exercise outside hospital, and his voice and mental outlook had changed to that of a healthy man confident in his health.

The improvement, as shown by the body-weight, the daily weight of the stools, and the blood picture, is depicted in fig. 1. From the third day of folic-acid treatment he passed only one daily motion, which was soft but formed and had lost the colour and offensive odour of the sprue stool. The total weight of fæces passed had fallen to an average of about 10 oz. daily, though occasional excessive stools continued for a week.

*A fractional test-meal the day after completion of folic-*acid therapy showed no free HCl in the fasting juice, a slightly increased excretion after the meal, and rapid emptying of

---

[1] Spies, T. D., Frommeyer, W. B., Garcia Lopez, G., Lopez Toca, R., Gwinner, G. *Lancet*, 1946, i, 883.

The course of events was subsequently reversed again when the patient was again emotionally reassured.

We must ask what common property can be found in the remissions of symptoms by such diverse means as succeed in these cases. This question applies not only to ulcerative colitis but also to some cases of asthma and to many cases of conversion hysteria. Physical agents may be various, and successful psychotherapy may come from various schools and vary much in personal handling. But the common features for the patient are two: (1) in the emotional field there is relief of anxiety; and (2) in the physical field there is relief of a dysfunction which, both in asthma and in colitis, is an overfunction of muscle—a muscular spasm.

Mechanism.—Moschcowitz (1943) has placed ulcerative colitis among "hyperkinetic diseases." Such diseases include essential hypertension, Graves's disease, peptic ulcer, cardiospasm, spastic colon, mucous and ulcerative colitis, manic-depressive psychosis, and paranoia. Their common pathology consists of an exaggeration of normal function. In ulcerative colitis the functions which are increased are tone, peristalsis, and secretion of mucus. Moschcowitz holds that in all hyperkinetic diseases the patient's ego is involved in a maladjustment with his environment.

An experimental attempt has been made to clarify the physical changes of ulcerative colitis by means of explants of the colon of the dog (Lium and Porter 1939). These experiments showed that ulceration of the mucosa could develop within twenty-four hours of the operation if the colonic muscle remained in spasm, and that the ulcers could heal again in 10–14 days if the muscle became relaxed. Colonic muscular spasm and hypersecretion of mucus are produced by various agencies, including mechanical stimulation, acetylcholine or other parasympathomimetic drug, and dysentery toxin. Thus Lium and Porter regard ulcerative colitis as "a specific reaction to a number of influences which can initiate spasm of the colonic musculature." They add that "once the colon becomes spastic it is an organ that can produce severe damage to its own surface structures." The radiological appearances of the "pencil colon" would make it easy to accept colonic spasm as a physical basis of ulcerative colitis, were it not that experienced clinicians incline to regard the "pencil colon" as a more common feature in those cases of colonic spasm which do *not* proceed to ulceration (Ryle 1945).

One further experimental observation deserves recording. It is that fright will cause pallor of the explanted colonic mucosa of the dog, and that additional, more localised, patches of pallor then follow mechanical stimulation (Drury et al. 1929). This reaction is not caused by adrenaline and occurs after adrenalectomy.

It does not then seem an improbable explanation of some cases of ulcerative colitis that anxiety causes muscular spasm and mucosal changes in an organ previously rendered susceptible either by a psychological or a physical sensitisation, or by both. The diarrhœal response to frank anxiety is well known; it is shown by many ulcerative colitis patients, including the present cases. But much of the anxiety of these cases is unconscious; it is part of their unconscious fantasy life. Deep anxiety over problems of emotional aggressiveness characterises both ulcerative colitis and asthma, and they betray their origins early in psychoanalysis. Asthmatics may have colonic spasm, or "colon neurosis," though apparently seldom or never ulcerative colitis (Ryle 1939, Hardy 1945). In both organs the response is parasympathomimetic.

The adrenaline-sympathetic response to emotions which are naturally productive of activity is well known. The emotional significance of overaction of the parasympathetic system is less well understood. From the psychological data it is arguable that that system mediates not only the anabolic phases of nutrition also deep mortal anxiety and fear-of-death complex such as can be found by the psychoanalyst to be associated with deeply repressed aggressive impulses and unconscious guilt. There is a sort of angor animi which occurs in asthma and also sometimes in cardiac neuroses with bradycardia, and a similar mechanism may occur in some cases of ulcerative colitis. But it seems as if psychological mechanisms that could turn one case of deep unconscious anxiety to asthma and another to ulcerative colitis must either be inherent or lie in very early environmental factors. The physical determinants of such organ sensitivities remain unknown.

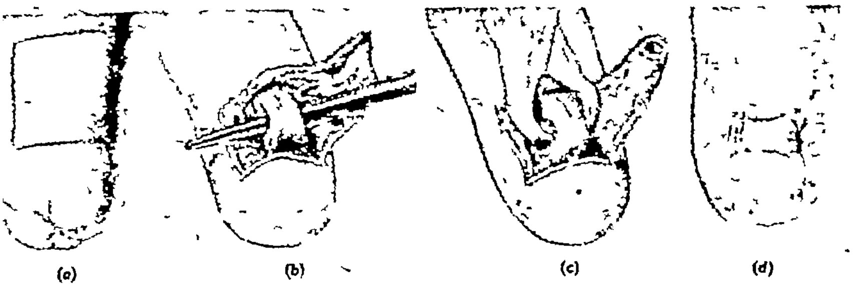
Principles of Treatment.—In the treatment of pathological anxiety accompanied by physical symptoms success may come quickly if the reassurance is intense enough. In all cases the immediate measure of success is the reduction of anxiety and removal of the symptom, the two going hand in hand and reacting on each other. I consider that to relieve anxiety more skilfully the physician should know enough of the Freudian unconscious to guess at some of the underlying psychological mechanisms of the case he is handling, though he must not display these to the patient beyond the stage of innuendo. Only experience can tell the therapist how far he can go without incurring a resistance and repudiation which may involve him in a long analysis. In my opinion this experience can be acquired by the general physician if he will submit himself to a comparatively short period of special training. In case 1, a man of rectal sensitivity who was also of pacifist tendencies, and had an ego-ideal of neatness, kindness, and pleasing others must be expected, ex hypothesi, to harbour problems of repressed aggressiveness. If he does so, his anxiety will almost certainly be connected with those problems. Thus the patient's apprehension over affronts against his person, property, and dignity must be handled with great sympathy, and much of his anxiety must be laid at the door of such affronts. When it comes to interpretation, it is also of immense value to an intelligent man to have an explanation of his bodily symptoms which is at once intelligible and physiologically true. On the other hand, too early or too deep psychoanalysis may expose more unconscious problems than it can alleviate and thus may aggravate, even dangerously, the course of the physical illness.

Essentially what cures a psychoneurotic is an emotional change and not an intellectual one. Anxiety has to give way to confidence in all cases. The feeling that "it's all right now" may come from faith alone, or through faith aroused by works, by increased self-knowledge, or by a soothing hand being laid on a tender spot of half-conscious anxiety or guilt. Arguments too may play their part. Intellectual mastery is one way to emotional satisfaction in the experience of all obsessional characters. There occur opportunities of giving acceptable interpretations and crucial reassurances at many stages in the voyage up that long river of access to the deeply unconscious mind which a traditional psychoanalysis pursues. The object of quick psychotherapy must be to recognise the earliest of those opportunities, steer towards it, secure good anchorage, and discharge cargo.

SUMMARY

A case of severe ulcerative colitis (case 1) is described in which relief followed two sessions of psychotherapy, relapse developed in response to an imagined callous affront, and a considerable measure of temporary "cure" was effected by calculated reassurances based on an assumed Freudian psychopathology.

Two subsidiary cases are recorded with resolution of the colitis, though one patient subsequently passed into a psychotic state in which guilt played a prominent part.



ig. 1—Making the skin tunnel: (a) flap outlined; (b) muscle tunnelled; (c) skin tubed; (d) tunnel through muscle skin-grafted.

Making the Tunnels.—The most important feature, fter having enough length, having muscle present in oth flexor and extensor groups, and having a movable erminal scar, is the making of good tunnels. This is done under local anæsthesia so that the best muscle roups may be selected for the tunnel. The operation akes about twenty minutes. Both tunnels and even oth arms may be done in one sitting.

An area of about three finger-breadths or about 5×5 sq. cm. is mapped out about 5 cm. from the end of the stump. Three sides of this square are freed to form a flap with its base either on the medial or on the lateral side (fig. 1*a*). The flap consists of skin and subcutaneous tissue including the deep fascia. This flap is next formed into a tube with the skin surface on the inside, the suturing being by subcuticular catgut so as not to pierce the skin surface (fig. 1*c*).

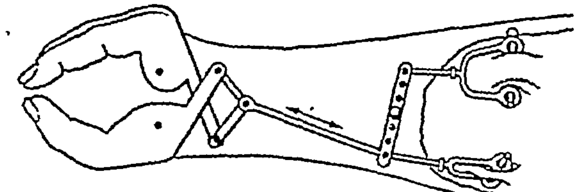


Fig. 2—Forearm mechanism.

The next step is to select the site for the tunnel in the muscle. It must be at right angles to the axis of the limb and in the plane of action of the muscles. On the extensor surface of the forearm it is parallel to the dorsal surface, but on the flexor surface it is at a slight angle with the plane of the radius and ulna, because the main muscle mass bulges more on the ulnar than on the radial side of the forearm. Next, a blunt-pointed muscle dilator is passed through the muscle-fibres along a track about 1·5 cm. long and 0·5–1·0 cm. deep, only a thin layer of muscle-fibres being picked up (fig. 1*b*). The tube of skin is then passed through this tunnel in the muscle and is fixed with three sutures to the skin edge of the side opposite the base of the tube. One suture is taken at each of the four corners of the raw area to close the angles somewhat. A Thiersch skin-graft is cut and sutured in place over the remaining raw area (fig. 1*d*). A soft-paraffin gauze wick is passed through the skin tunnel, and the skin-graft is suitably dressed.

The first dressing is done in ten days. Then the pins, 5–10 mm. in diameter, are inserted. The patient is instructed in care of the skin tunnels with cleansing, alcohol, and powder. Exercises are maintained, and in about three months an artificial limb is fitted.

THE PROSTHESIS

The artificial limbs are of light aluminium covered with leather. There are windows where the pins emerge to be attached to a metal loop at each end (fig. 3). The mechanics of the elbow and hand mechanism are somewhat intricate. The principle of the limb for the forearm is illustrated in fig. 2, and for the upper arm in fig. 4. In the forearm, contraction of the flexor group opens the hand, and contraction of the extensor group closes the hand. In the upper arm, contraction of the biceps closes the hand, and contraction of the triceps opens the hand; a strap from the ipsilateral shoulder pronates the hand, and a spring supinates it again; a strap from the contralateral shoulder flexes the elbow, and gravity extends the elbow. There are locking devices, easily manipulated by buttons on the outside, that lock the elbow in a fixed position, and the forearm in a fixed position of rotation, if desired; and there is one at the wrist that locks the hand grip. It is arranged so that

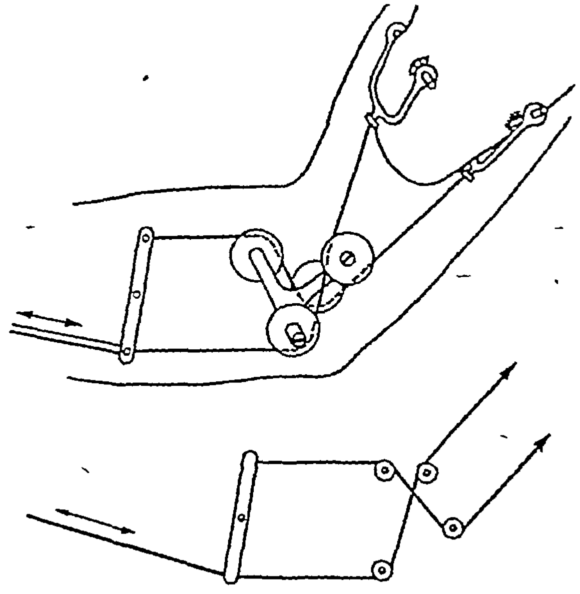

Fig. 4—Upper-arm mechanism.

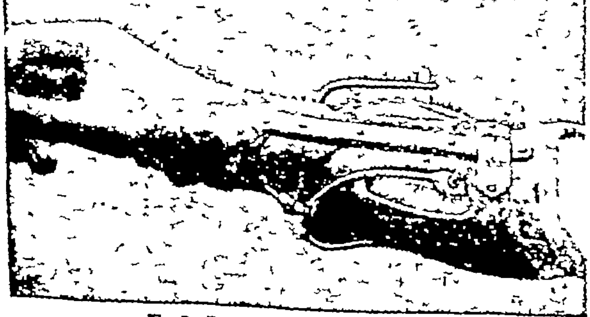

Fig. 3—Right forearm artificial limb.

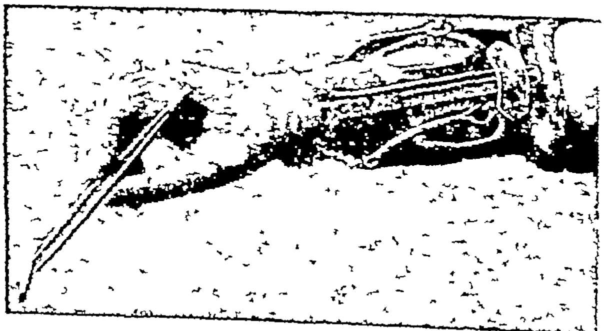

Fig. 5—Patient picking up match with forceps.

the stomach (fig. 2). A fortnight later the test was within normal limits (fig. 3).

DISCUSSION

A minimal amount of folic acid was used—one phial of ten 5 mg. tablets, which was all that could be obtained. Other clinicians in U.S.A., notably Spies et al.[1] and Vilter et al.,[2] have studied the effect of folic acid on the macrocytic anæmias, using doses as high as 100 mg. daily and a total course of over 1000 mg. Such extravagance is still impossible in this country.

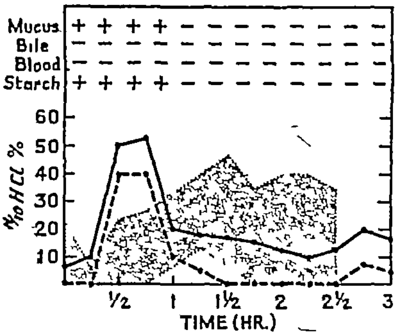

Fig. 2—Test-meal findings on the day after completion of course of folic acid.

Perhaps such large doses are necessary to obtain prompt hæmopoietic response in cases in which macrocytic anæmia has long been untreated and folic acid is a substitute for liver therapy. Spies emphasises the importance of ensuring that no previous treatment is still acting during the experimental period.

This report, however, primarily concerns the nature of the stools and the well-being of the patient. The hæmopoietic response was pronounced but not dramatic, owing to the long previous liver therapy and the consequent absence of very severe macrocytic anæmia at the start. Nevertheless, some credit must be given to the folic acid, since the previously resistant anæmia then started to improve and continued to improve after the resumption of liver injections.

Similarly, the immediate improvement of the stools was most remarkable; and, though there were subsequently a few days when they were too bulky, diarrhœa did not recur, and a fairly constant daily total amount of fæces was passed, which on analysis of the dried stool for fat gave figures compatible with normal (fig. 1). This may have been due in part to the improvement in the anæmia, but there is no doubt that folic acid was the immediate cause of the improvement, and that this continued even after folic acid had been withdrawn.

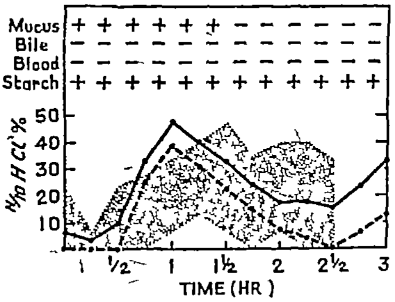

Fig. 3—Test-meal findings a fortnight later than in fig. 2.

Perhaps folic acid may provide the switch by which the vicious circle of these diseases can be reversed, after which further recovery can continue without its aid.

SUMMARY

A case of tropical sprue, which had resisted the usual treatment for two years in India and England, was treated with folic acid, 10 mg. daily by mouth for five days, whereupon there was a very rapid and great improvement, which has been maintained since the folic acid was discontinued. The patient now (Nov 21) weighs 10 st. 7 lb. and is in perfect health.

SAUERBRUCH CINEPLASTIC AMPUTATION

R. K. MAGEE
B.A., M.D. Toronto, F.R.C.S., F.R.C.S.(C)
MAJOR R.C.A.M.C.; SURGEON, PETERBOROUGH CLINIC, ONTARIO

THE cineplastic amputation of Sauerbruch was described at the International Conference on Amputations in Ottawa in 1943 by Kassler, who is one of its exponents in America. A recent visit to Sauerbruch's clinic in Berlin enables me to describe the method used there now, including modifications introduced since 1943. Prof. P. Gohrbandt, chief assistant at the clinic, kindly arranged for surgeons, limb-makers, secretarial staff, interpreters, and patients to give their full time to completing this survey. There were some 30 inpatients awaiting some phase of the treatment, and the study included photographs to illustrate the principles of the operation and of the prosthesis used.

SELECTION OF CASES

The cineplastic amputation is applicable only in the upper limb. As is well known, the success of an artificial limb depends primarily on the patient's will to succeed. As a result, the dexterity achieved with the limb is enhanced in bilateral cases, where the patient is forced to use the limb, and it is greatest in the more intelligent patients. Accordingly the cineplastic amputation is chosen more for bilateral cases and with consideration for the patient's intelligence and the type of work he will be doing, though some believe it is the best amputation with adequate screening even in unilateral cases, provided that patients without the necessary intellect or will to succeed are excluded.

The youngest patient in whom this method was used was 8 years old. The shortest stump in the forearm in which it may be used is 7–8 cm. from the anterior elbow crease. In shorter forearm stumps a tilting ring type is used with the same hand mechanism. The best results are obtained in forearm amputations, but upper-arm amputations may give nearly as good ones.

PRINCIPLE

Unlike earlier methods of suturing tendons into loops and covering them with skin, the principle now adopted consists of making skin-lined tunnels through the flexor and extensor groups of either arm or forearm muscles (fig. 1). Through each tunnel is passed an ivory pin, which is connected by a chain to a bar, much as the two traces are used in harnessing a horse to a cart. From the lower end of this bar a metal rod goes to the hand mechanism. The hand mechanism operates like a Cornet's forceps of which one side is the thumb and the other side the index finger and the rest of the hand. Thus, pushing forward on the rod opens the hand, and pulling back on the rod closes the hand and approximates the thumb and index finger with a grip of appreciable power (fig. 2).

METHOD

The sine qua non of this operation is a movable scar at the end of the bones, inasmuch as the degree of up-and-down movement of the pins determines the extent of opening and closing of the hand that will result. Since many amputations were done under war conditions and have fixed scars, reamputation is often the first step. The bones are divided 2–3 cm. shorter than the muscles; and the deep fascia, but not the muscles, is sutured over the ends of the bones to give a free scar. Within 5–10 days active exercises and massage are instituted, and constant practice is insisted on so that the patient learns to pull the terminal scar backwards and forwards.

Medical Societies

ROYAL SOCIETY OF MEDICINE

THE psychiatry section met on Dec. 10, with Prof. AUBREY LEWIS, the president, in the chair, to discuss

Leucotomy as an Instrument of Research

Dr. A. MEYER and Dr. T. MCLARDY showed from observation of 27 brains how great are the unintentional variations in the leucotome's cut. The bilateral lesion through the whole of the white matter, generally aimed at, is rarely attained; the most medial regions of the white matter are seldom involved, and the striate body is often damaged.

Interruption of the thalamo-frontal radiation connecting the dorsomedial nucleus of the thalamus with the prefrontal region is widely considered to constitute the rationale of prefrontal leucotomy. Walker concluded from his study of this projection in monkeys that a dorsoventral axis of the prefrontal lobe corresponds roughly to a lateromedial axis of the dorsomedial nucleus. Dr. Meyer's observation of human brains has confirmed the existence of an organisation similar to but more complex than that described by Walker; the projection of the magnocellular part of the nucleus is limited to the medial half of the orbital cortex, comprising area 12 and part of area 11. Since the magnocellular nucleus is connected with hypothalamic centres, it may be assumed that this orbital projection forms part of a pathway serving autonomic functions—a pathway which may well furnish the substrate for recent physiological findings from which workers have postulated a vagal cortical representation in the orbital region. This pathway might explain some of the autonomic changes which may occur after prefrontal leucotomy.

As regards long association fibres, prefrontal leucotomy should involve the superior frontal, cingulate, subcallosal, uncinate, and inferior fronto-occipital fasciculi. So far, said Dr. Meyer, degeneration has been seen only in the uncinate, the cingulate, and the most medial part of the superior longitudinal fasciculi.

The concepts of localised and holistic mental function are not mutually exclusive; they are complementary. The psychiatrist has long been accustomed to a pluridimensional approach to diagnosis; in other words, the results of cerebral lesions must be evaluated in relation to the individual's constitution, life history, age, and present environment. The contention that the frontal lobes are particularly concerned in the highest mental activities would seem to require qualification in the light of recent work; for instance, the volume of the frontal lobe is not significantly greater in man than in the chimpanzee—in striking contrast to the temporal and parietal lobes which steadily enlarge from monkeys to man. A specific personality change from frontal-lobe lesions has not been generally accepted: further studies of leucotomy should give a decisive answer.

ELECTROENCEPHALOGRAPHIC STUDIES

Mr. G. D. GREVILLE, PH.D., and Dr. S. L. LAST said that in 35 cases operated on by Mr. G. C. Knight, using Freeman and Watts's together with Crombie's technique, it was found that after operation the voltage of the alpha rhythm (8–13 cycles per second) tends to increase, as also does the amount; these changes may be due to better relaxation. On the other hand, the voltage of the fast activity (over 13 cycles per second) tends to decrease, as does its amount.

Delta activity (under 4 cycles per second) was found at one time or another in more than half the cases; it usually appears, if at all, one day after operation, and certainly within the first ten days. Immediately after operation it may occur all over the cortex, but soon it becomes prominent in the frontal areas; there may then be some extension to central areas, but this gradually disappears during the first three weeks. The material shows no correlation between age and the occurrence of delta rhythm; but this rhythm appeared a little more often in those with clinical improvement than in those with none.

Theta rhythm (4–7 cycles per second) is more common than delta and tends to persist much longer.

AUTONOMIC CHANGES

Dr. F. REITMAN reported an investigation of vagus function after leucotomy. Operation, he said, is followed by a slight increase in the total gastric acidity; the peak of total acidity is reached earlier, and the emptying-time is quicker. Moreover the total volume of gastric juice following the intravenous injection of 'Prostigmin' 1 mg. is greater after operation.

MENTAL FUNCTION

Dr. M. B. BRODY said that patients do intelligence tests as well after as before operation. Nor is there evidence of deterioration in abstract thinking, as judged by the Goldstein tests. Goldstein, however, has reported deterioration, basing his conclusion on an analysis of behaviour. It would seem that after leucotomy the capacity is unimpaired but that the patient does not use it except under the stimulus of test conditions. The prefrontal area thus plays no part in mental tests. It may be that the capacity depends on integrated activity of the cortex as a whole or on some area other than the cortex: in Pick's disease, for example, mental changes are correlated with changes in the dorsomedial nucleus of the thalamus. It may be that ideation is intellectualised emotion. What is needed is a standardised approach to the study of all mental changes.

New Inventions

MUSCLE FORCEPS FOR SQUINT OPERATION

THE instrument (fig. 1) is built as an artery forceps and has two catches. It grips the muscle firmly and does not slip. The shanks are bent at an angle of 30° so that the hand controlling the forceps is not in the way of the hand holding the hook. The blades have notches on both edges to guide the needle, and should be applied so that the notches are symmetrically disposed in relation to the muscle.

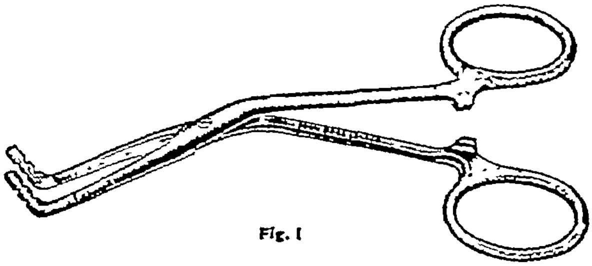

Fig. 1

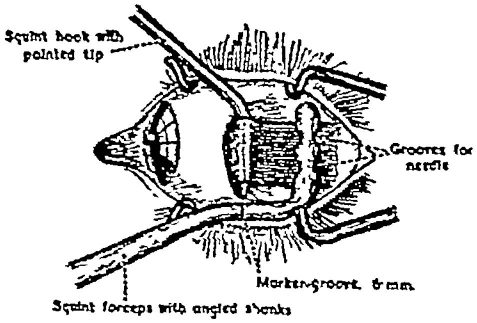
The shaft of the forceps is grooved 6 mm. from the proximal edge of the blades. This mark, in conjunction with a pointed hook, can be used for measuring or estimating the distance from the line where the forceps grips the muscle.



Squint hook with pointed tip
Grooves for needle
Marker-groove, 6 mm.
Squint forceps with angled shanks

Fig. 2

Fig. 2 shows the use of the instrument during operation. Naturally, the hook can be inserted from beneath, and the forceps from above, if preferred. Both the forceps and the hook have been made for me by Down Bros. and Mayer & Phelps Ltd.

M. KLEIN, M.D. Pécs, D.O.M.S.
Associate Surgeon and Biochemist,
Central London Ophthalmic Hospital.

the muscles grasp an object—e.g., a pencil—between the thumb and opposing hand, then by locking the hand mechanism the grip will be maintained without muscle effort (fig. 5). The hand can close further but cannot open.

RESULTS

Patients at Sauerbruch's clinic demonstrated the movements that they had learnt. They could write with normal legibility and could pick up a match with forceps (fig. 5) or with the hand, pick out a cigarette and light it, and attend to their clothes. They showed the strength of the limb by lifting up and carrying a pail of water. Some described the development of a sense of touch whereby they could distinguish, for example, a watch from a pencil in a pocket. One patient with both forearms amputated had been a switchboard operator at the hospital for some years but had been killed by a bomb.

CONCLUSION

The cineplastic amputation as developed by Sauerbruch appears to have the advantage of permitting more dexterous movements under more normal muscle control than prostheses utilising special accessories for special routine tasks. To the intelligent man with a bilateral amputation of the arm or forearm this may offer a wider range of less stereotyped activity, which may open to him wider spheres of enjoyment and employment.

RETINAL MECHANISM OF VISION

F. W. Edridge-Green
C.B.E., M.D. Durh., F.R.C.S.
SPECIAL EXAMINER AND ADVISER ON VISION AND COLOUR VISION TO THE MINISTRY OF TRANSPORT

A SIMPLE experiment shows that the stimulus in vision is photochemical and movable in the retina. If a bright light on a dark ground is looked at for the shortest possible time, with one or both eyes, and then the eyes are closed and covered, a positive after-image of the light will be seen. If the eye or eyes are moved *to the right*, the positive after-image will change its relative position in the field of vision, moving to the right of the negative after-image which is seen clearly defined at the fixation point. The positive after-image is distorted, but not the negative.

When an object is moved in front of the eyes, and the eyes are kept still, multiple objects are seen, owing to the persistence of vision, which is the basis of cinematography. This persistence of vision is due to the positive after-image, as can be shown by numerous experiments. It will be noted that there is no apparent persistence of vision when the eye is moved—not even a trace of a blur. If there were persistence of vision when the eyes are moved it would be difficult to read, because the type would appear confused, as it does when a book is moved in front of the eyes.

The positive after-image which causes persistence of vision can be seen when it is looked for. When the eye is moved to the right, the external rectus, on contracting, besides moving the eye to the right also presses on the back of the eye, *shifting the photochemical fluid* in the interretinal space to the right, so that the image of the *object appears* to the right of the fixation point. This image appears distorted and may even appear broken up. Thus a small chromium clock will appear distorted though clearly recognisable. If a small red square 1 cm. × 1 cm. is viewed at a distance of 2 metres on a white ground, and then is shifted rapidly to the left, it will be followed by several red spots resembling the microscopical appearance of the cones in the retina.

An easy method of seeing the shifting of the positive after-image is as follows. A white flower is placed on the right of a red one and viewed at a distance of 3 metres. If the observer looks first at the red flower and then transfers his gaze immediately to the white one, the white flower will be seen clearly, but the red positive after-image of the red flower will be seen on the right of the white flower.

In the past there has been much discussion about why moving objects are occasionally seen quite clearly momentarily, as if stationary, but the conditions in which this occurs can be defined. When the eyes have been moving and suddenly fixate a moving object, they momentarily see this object quite clearly, as can be seen with a speaker in a cinematographic picture, or a moving cricket or tennis ball.

FUNCTION OF THE INTERRETINAL FLUID

Vision takes place through sensitisation of the fluid in the interretinal space which surrounds the cones. This fluid is sensitised by the visual purple, the rods not being percipient elements but the nerve elements regulating the sensitising of this fluid. The cones are the sole percipient elements, but they are sensitive not directly to light but only to the photochemical changes in the liquid surrounding them. The response to the perception of form corresponds to the cone distribution of the retina. Marshall and I have seen and demonstrated the visual purple in liquid form surrounding the cones in the fovea (Marshall and Edridge-Green 1902). Kühne (1878) found the visual purple in liquid form in the retina of a shark, but he did not recognise the significance of the observation. The remarks of Hartridge (1946), therefore, can only apply to the cones.

I have always classified the defects of colour perception of mankind according to the number of distinct colours seen in a bright spectrum, naming them as heptachromic, hexachromic, pentachromic, tetrachromic, trichromic, dichromic, and totally colour-blind.

The fovea may at one moment be the most sensitive part of the whole retina, and the next moment the least. Various currents in the field of vision, not due to the circulation, are due to the flow of currents of sensitised retinal fluid.

In certain conditions the central portion of the retina becomes insensitive to light while the remaining portions remain sensitive. If a piece of black velvet is attached to a dark door, and a pin in the centre of the velvet is viewed from a distance of 3 metres in a dull light, the velvet *and then the door* will disappear, the wallpaper appearing to meet over the door, with corresponding contraction of the field of vision.

If a piece of black cardboard about 30 cm. × 15 cm. is placed on a persian carpet or wallpaper, and viewed at a distance of 3 metres in a dull light, the pattern of the carpet or wallpaper will appear to invade the black cardboard until the whole card seems to be covered by it. The cardboard appears to have become transparent, *and the carpet appears to be visible through it.*

The influence of one colour on another may be seen if on half of a pale purple ground there is a bright green pattern, and on the other half a bright purple pattern. The ground with the green pattern will appear green, and the ground with the purple pattern purple. Or if one takes two strips of pure green and places two yellow strips adjacent to one green strip, and two violet strips adjacent to the other, the green with the yellow *adjacent will appear yellow-green, and the green adjacent* to the violet will appear blue-green or blue.

None of the above observations is idiosyncratic. Each had been confirmed many times before publication by observers who did not know what they were expected to see.

An Introduction to Clinical Surgery

CHARLES F. M. SAINT, M.D., M.S., F.R.C.S., F.R.A.C.S., professor of surgery, University of Cape Town. Cape Town: for the Postgraduate Press by the *African Bookman*. Pp. 293. *25s.*

Prof. Charles Saint is due to retire after 25 years of surgical teaching at the University of Cape Town. Those who served with his students in the Middle East and Italy, and saw the care of the wounded in South Africa, know of the high standard of his teaching. This book is a fitting epilogue to his labours. Disciplined in the school of Rutherford Morison, Professor Saint believes that the student must not only appreciate nature's methods but must get the habit of orderly examination of the patient; he must learn that diagnosis is not for the sauntering gaze, that "spot" diagnosis is an evil, and that the mechanism of the patient's pain must be analysed. To illustrate these principles he has packed into this book a mass of clinical experience, described in memorable phrases: "A firm narrow tongue with a point like a spearhead usually indicates good health and a good appetite"; "in the small breast there is much less intervening tissue to traverse before dissemination occurs"; "the patient attaches much more importance to the claudication than to the ulcer on his toe, whereas actually the toe condition is far more serious from the angle of preservation of the limb and possibly his life." Two outstanding chapters are on appendicitis and peripheral vascular disease.

The main responsibility of the surgical teacher should be the quickening of all the senses of the student, and among these Professor Saint includes common sense. That quality, above all others, pervades his book.

Milk: Production and Control

(2nd ed.) WM. CLUNIE HARVEY, M.D., D.P.H., M.O.H. for Southgate; HARRY HILL, F.R.San.I., A.M.I.S.E., F.S.I.A., sanitary inspector for Axbridge R.D.C. London: H. K. Lewis. Pp. 512. *37s. 6d.*

THERE have been numerous changes since 1935 in the handling of milk, many of which are described in this book. The chapter on heat treatment, including a description of the new high-temperature short-time process, will be valued by medical officers of health and sanitary inspectors; and, as before, the chapter on milk legislation is a handy compendium. Methods of cleaning rail and road tanks are not considered, though they are of some concern to the dairies in many of our large cities; and the section on bottle-washing is a little disappointing. The recommendation that the final treatment of all bottles should consist in sterilisation by steam is impracticable with the continuous method of processing and bottling. More attention might perhaps have been paid to the design of milk bottles, particularly with respect to the pouring lip; but taken as a whole the book remains a useful guide, and this second edition is welcome.

Les phénomènes d'allergie non spécifique dans la tuberculose et les fièvres typhoïdes

JEAN ALBERT-WEIL. Paris: Librairie Maloine. Pp. 83.

THIS essay on the pathogenesis of infectious diseases, with special reference to tuberculosis and typhoid fever, is largely a review of the published work bearing most nearly on the author's view that non-specific allergy contributes as much to the production of disease as do specific factors. Inspired by a lecture of Prof. R. Leriche, he accepts the view that the various mechanisms of allergy play an important part in the fundamental processes of infectious diseases. Except in overwhelming infections the make-up of the patient—his diathesis—contributes considerably to the severity of the disease; in certain cases there would be little or no illness following infection but for the responses of the body. The anatomical lesion causes satellite phenomena of a vasomotor type which may be of more clinical importance than the anatomical lesion itself. In the production of such a disease as tuberculosis specific allergic reactions play their part; but non-specific allergy and the reactions of a hypersensitive vegetative nervous system are responsible for certain pathological processes such as the hæmorrhagic complications of infectious diseases. The mechanisms of non-specific allergy are not well known, and this book presents them fully and lucidly with special reference to the phenomena of Sanarelli and Shwartzman. In non-specific or hetero-allergy the animal is sensitised to one substance and reacts allergically to others. The sensitising or "preparatory" substance is of the nature of a complete antigen; the second or "provoking" substance is a simpler chemical and includes a wide range of substances such as starch, agar, bacterial preparations, and animal sera. Dr. Albert-Weil's theory is that such a mechanism plays an important part in the onset and evolution of lesions. He follows Friedmann in attributing hetero-allergy to a reaction not of the tissues but of the vegetative nervous system, which, in the course of many infections, acquires a sensitivity to many antigens. The provoking substance may be organisms other than the specific causal agent of the disease; but his emphasis on *Bact. coli* as a common agent in the pathogenesis of disease is reminiscent of a phase of British medicine which passed with the death of a famous surgeon.

Diabetes

A Concise Presentation. HENRY J. JOHN, M.D., F.A.C.P., lieut.-colonel M.C.A.U.S., Cleveland, Ohio. London: H Kimpton. Pp. 300. *17s.*

THIS is a difficult book to review fairly. It aims at helping "the busy practitioner to rationalise and to utilise the current knowledge on diabetes," but it often tackles diabetic problems with too much theoretical and too little practical detail. The English is not very clear, some sentences having no subject and almost no object. The book covers the usual range of diagnostic tolerance tests, insulin, diet, and so on, but its practical dictates are not well arranged or easy to find. Nevertheless there is much of interest to read of Dr. John's long and wide experience of diabetes. He has always been interested in glucose-tolerance tests, and his definition of the normal is that generally accepted. What makes the book fresh and unusual is his constant recourse to the particular and the personal—detailed descriptions of his cases and personal remarks about them. The whole book is interlarded and enlivened by these reminiscences. His personal tastes and interests predominate and make sections on hyperthyroidism and the salivary glands full and absorbing, whereas subjects of such importance as cardiovascular and eye complications are not even listed in the index. It is hardly a practical book, and certainly not a reference book, but it is an interesting expression of the personality and vitality of the author.

First Aid to the Injured

(Supplement.) St. John Ambulance Association. Pp. 32 *6d.*

THE last issue of the "First Aid Textbook" of the St. John Ambulance Association was published in 1937; this short supplement embodies the knowledge gained by the experiences of the late war. There is a good account of shock, emphasising that the patient must go to hospital because he will almost certainly need transfusion. The dangers of overheating are well stressed. For transport of the fractured spine the supine position is advocated: though it is not made clear why there should be any greater risk in leaving him in the prone position, into which he will usually be turned for reduction of the fracture. Good rules are given for the treatment of the incised wound, on the use of local pressure, and on elevation of the limb to cope with venous oozing. Advice on the treatment of burns is to avoid the breaking of blisters, apply only saline or soda bicarbonate solution, meddle as little as possible, and keep the patient warm. The special appendix on the rocking-stretcher method of artificial respiration is also sound: "commence Schafer's method of artificial respiration. Do not take the patient to the rocking stretcher; the stretcher must be brought to the patient." Medical students might profitably study the diagram on the last page showing how to arrange the blankets to keep the patient warm; this method could be used for patients leaving the operatin

Risk or Opportunity ?

THE profession has given the negative answer. Why ? Firstly, because the leaders of the British Medical Association have presented a partial picture f the National Health Service scheme, continually mphasising its risks and imperfections rather than its opportunities. Secondly, because practitioners are ndignant at the Minister's handling of the dispute over insurance capitation fees. Thirdly, because t was widely, if erroneously, felt that proper consultations had never been held. Fourthly, because Mr. BEVAN would not renounce the basic salary, though this was not essential to his project. Fifthly, because Willesden provided a gratuitous example of political interference in medical work. Sixthly, because restrictions, controls, and loss of privileges have bred in the middle classes a mood of irritation in which they gladly canalise their grievances through the answer No. Lastly, because the Act gives the Minister power to create a bad service (Not a conclusive reason, perhaps, for refusing to help him to create a good one.)

When the B.M.A. council met last week its more experienced members must have known that the majority—then thought to be 56–44% but now nearer 54–46—does not justify non-coöperation with the Government of the day. They must have known how resistance at this stage would strike the public, which is tired of sectional bodies that prefer direct action to negotiation. On the other hand, if they decided to continue negotiations they would have the unenviable task of explaining to their constituents why the majority vote was being ignored. If the necessity for a two-thirds or three-quarters majority had been explained before the plebiscite, the rupture of negotiations could have been averted. As it was, a situation has been allowed to develop in which the B.M.A. finds itself standing bravely, on untenable ground, with little over half its forces mustered.

The council's decision has yet to be ratified by the special representative meeting called for the end of January. But the representative body of the association is representative only in the sense that it represents the majority in each division,[1] and, since the distribution of Yes and No is fairly even throughout the country, the large minority will as usual have few spokesmen. We may take it therefore that the B.M.A. has now effectively dissociated itself from the shaping of the National Health Service at its present most critical stage, and that it will discourage doctors from advising the Minister or accepting any kind of appointment such as membership of a regional board. But though the association held 16 out of the 32 places on the Negotiating Committee, there are a number of other constituent bodies which may have different opinions about the proper attitude of the profession at this moment. For example, judging by their attitude so far—which seemed to find no expression in the committee's report sent out with the voting papers—the governing bodies of the English colleges are unlikely to refuse counsel to the Minister on matters within their own sphere. Where he is deprived of the help of official bodies, Mr. BEVAN can turn to unofficial advisers—who will at least have the merit of wanting the Act to succeed—or can evolve regulations within his own office. The one action he cannot possibly be expected to take is to introduce an amending Bill as prescribed by Dr. DAIN.[2]

Though the Minister cannot go back to Parliament and ask it to reverse major legislative decisions, he could conceivably compromise with the B.M.A. by altering the time-table of his scheme. This is the proposal lately made by Sir HENRY BASHFORD,[3] who suggested that the Government should go ahead with their plans for hospital and specialist services but should leave general practice as it is. In so doing they would be following advice given to their predecessors by Lord DAWSON and others who wanted progress by stages: moreover, any good compromise has charms for men of good will, especially at the present season. But the Government's programme of social reform has now gone so far that only the united opposition of the profession could enforce such a capitulation. The Bashford plan would do nothing to remove the economic barrier preventing housewives and children from seeking early aid from their doctor; indeed by providing a free hospital service it might lead patients to short-circuit general practitioners whenever they could. It would do nothing to distribute doctors better, to equip them better, and to encourage their coöperation with each other or with public-health workers, or to employ demobilised doctors satisfactorily. Nor would it provide machinery through which the new benefits of the National Insurance Act and the National Health Service Act could be satisfactorily administered. The compromise, in fact, will not serve.

The Minister announces that the full scheme for a comprehensive medical service goes forward. It remains for him to persuade us that it will preserve those things we rightly value: but in confining its present rôle to destructive criticism the principal medical organisation has made a mistake; and unless the representative body reverses this decision the profession will be split. Even so, however, there need be no more than a sober agreement to differ for the time being. When the scheme is complete enough for judgment there will be a chance for united participation, or united opposition, based on facts rather than emotion; and in either case the profession could regain its effective unity. Meanwhile, with so close a division of opinion on policy, the majority will be wise to refrain from accusations of disloyalty against colleagues who mostly have the same causes at heart. Everyone who understands this conflict will recognise that honest and intelligent people can hold opposite views about it. To some it is natural to emphasise risks, to others opportunity. For our own part we see in the new service a chance of realising great aims. All forms of organisation are alarming and may be dangerous to freedom; but those who concentrate on the dangers of standardisation and regulation forget the strength of the English genius for liberty,

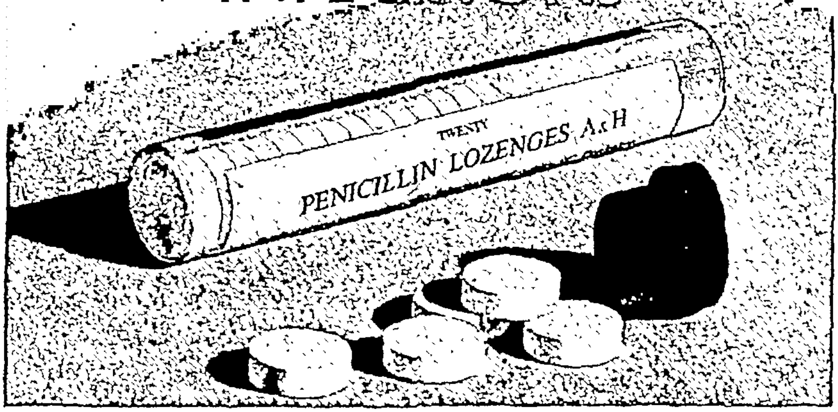
RATIONAL THERAPY IN BUCCO-PHARYNGEAL INFECTIONS



The Twenty-Lozenge Pack

Penicillin Lozenges A & H are issued in glass tubes to prevent inactivation of the penicillin by atmospheric moisture.

The number of lozenges contained in the tube (TWENTY) provides the most suitable package to meet the needs of individual treatment prescribed by the physician. Not only does it tend to eliminate waste but it assures the prescriber that the lozenges will not have time to become inactivated by exposure to a moist atmosphere before the prescribed treatment is completed.

Penicillin Lozenges A & H are indicated for the effective local treatment of bucco-pharyngeal infections.

In tubes of 20 Lozenges

Risk or Opportunity?

THE profession has given the negative answer. Why? Firstly, because the leaders of the British Medical Association have presented a partial picture of the National Health Service scheme, continually mphasising its risks and imperfections rather than its opportunities. Secondly, because practitioners are ndignant at the Minister's handling of the dispute over insurance capitation fees. Thirdly, because t was widely, if erroneously, felt that proper consultations had never been held. Fourthly, because Mr. *BEVAN would not renounce the basic salary*, hough this was not essential to his project. Fifthly, because Willesden provided a gratuitous example of political interference in medical work Sixthly, because restrictions, controls, and loss of privileges have bred in the middle classes a mood of irritation n which they gladly canalise their grievances through the answer No. Lastly, because the Act gives the Minister power to create a bad service (Not a conclusive *reason, perhaps, for* refusing to help him to create a good one.)

When the B.M.A. council met last week its more experienced members must have known that the majority—then thought to be 56–44% but now nearer 54–46—does not justify non-cooperation with the Government of the day. They must have known how resistance at this stage would strike the public, which is tired of sectional bodies that prefer direct action to negotiation On the other hand, if they decided to continue negotiations they would have the unenviable task of explaining to their constituents why the majority vote was being ignored If the necessity for a two-thirds or three-quarters majority had been explained before the plebiscite, the rupture of negotiations could have been averted As it was, a situation has been allowed to develop in which the B.M.A. finds itself standing bravely, on untenable ground, with little over half its forces mustered.

The council's decision has yet to be ratified by the special representative meeting called for the end of January. But the representative body of the association is representative only in the sense that it represents the majority in each division,[1] and, since the distribution of Yes and No is fairly even throughout the country, the large minority will as usual have few spokesmen. We may *take it therefore that the* B.M.A. has now effectively dissociated itself from the shaping of the National Health Service at its present most critical stage, and that it will discourage doctors from advising the Minister or accepting any kind of appointment such as membership of a regional board. But though the association held 16 out of the 32 places on the Negotiating Committee, there are a number of other constituent bodies which may have different opinions about the proper attitude of the profession at this moment For example, judging by their attitude so far—which seemed to find no expression in the committee's report sent out with the voting papers—the governing bodies of the English colleges are unlikely to refuse counsel to the Minister on matters within their own sphere. Where he is deprived of the help of official bodies, Mr. BEVAN can turn to unofficial advisers—who will at least have the merit of wanting the Act to succeed—or can evolve regulations within his own office. The one action he cannot possibly be expected to take is to introduce an amending Bill as prescribed by Dr. DAIN.[2]

Though the Minister cannot go back to Parliament *and ask it to reverse major legislative decisions*, he could conceivably compromise with the B.M.A. by *altering the time-table of his scheme. This is the* proposal lately made by Sir HENRY BASHFORD,[3] who suggested that the Government should go ahead with their plans for hospital and specialist services but should leave general practice as it is. In so doing they would be following advice given to their predecessors by Lord DAWSON and others who wanted progress by stages: moreover, any good compromise has charms for men of good will, especially *at the present season.* But the Government's programme of social reform has now gone so far that only the united *opposition of the profession could* enforce such a capitulation. The Bashford plan would do nothing to remove the economic barrier preventing housewives and children from seeking early aid from their doctor; indeed by providing a free hospital service it might lead patients to short-circuit general practitioners whenever they could. It would do *nothing to* distribute doctors better, to equip them better, and to encourage their coöperation with each other or with *public-health workers*, or to employ demobilised doctors satisfactorily. Nor would it provide machinery through which the new benefits of the National Insurance Act and the National Health Service Act could be satisfactorily administered. The compromise, in fact, will not serve.

The Minister announces that the full scheme for a comprehensive medical service goes forward. It remains for him to persuade us that it will preserve those things we *rightly* value: *but* in confining its present rôle to destructive criticism the principal medical organisation has made a mistake; and unless the representative body reverses this decision the profession will be split. Even so, however, there need be no more than a sober agreement to differ for the time being. When the scheme is complete enough for judgment there will be a chance for united participation, or united opposition, based on facts rather than emotion; *and in either* case the profession could regain its effective unity. Meanwhile, with so close a division of opinion on policy, the *majority* will be wise to refrain from accusations of disloyalty against colleagues who mostly have the same causes at heart. Everyone who understands this conflict will recognise that honest and intelligent people can hold opposite views about it. To some it is natural to emphasise risks, to others opportunity. For our own part we see in the new service a *chance* of realising great aims. All forms of organisation are alarming and may be dangerous to freedom; but those who concentrate on the dangers of standardisation and regulation forget the strength of the English genius for liberty, inequality, and multiformity. They forget, too, the inherent strength of our own calling.

[3] *Times*, Nov. 19, p. 5.

In face of opportunity a provisional Yes is better than a final No. We need "the faith of the sail, not of the anchor."

Postoperative Chests

THE chest complications of operations are an evergreen topic among surgeons and anæsthetists, and have been the cause of acrimonious discussions without number. It is now generally accepted, albeit grudgingly, that a postoperative chest complication is more likely to be due to the hand in the abdomen than to ether in the lungs. As Brock [1] says, "to imagine that the simple replacement of inhalation anæsthesia by local or spinal . . . will avoid such a complication shows a child-like faith born of inexperience or insufficient observation." Yet many anæsthetists and surgeons still believe that the particular routine they adopt in abdominal operations confers immunity to chest complications, despite the evidence drawn from painstaking observation and statistical analysis. Dripps and Deeming [2] now take up the battle-stained cudgels once more. They report that in one series of 250 abdominal operations the incidence of postoperative atelectasis was nearly three times as high (11%) after inhalation anæsthesia as after spinal (4·2%). "Since it has been conclusively proved by many investigations that the anæsthetic agent and technique are not major factors in postoperative morbidity," they remark, "it was evident that something was wrong." They were right: something was wrong. Investigation showed that the administration of these anæsthetics was left to nurse anæsthetists and junior interns, while the postoperative care of the patients from the point of view of "chests" was, to put it mildly, haphazard. In a second series of 990 upper abdominal operations the incidence of atelectasis after spinal anæsthesia remained virtually unchanged (5%), while that after inhalation anæsthesia had now fallen to 4·1%. In this second series, however, the anæsthesia and postoperative care were conducted by specialists.

During the last decade fashions have been sweeping anæsthesia, each purporting to be more "modern" than its predecessor. During each fashion wave the toast of the moment invariably possesses the virtue of conferring freedom from "chests." There is no little danger with this background that the once-scotched idea may again take root—that postoperative chests can be banished by curare, 'Pentothal,' local, spinal, or what have you. To believe that any one drug or method, even if labelled "modern," will by itself prevent a postoperative chest condition is to forget the knowledge and experience laboriously gathered by two generations of anæsthetists and surgeons. Two outstanding papers of recent years, for example, one statistical by King [3] and the other clinical by Brock,[1] convincingly show that the factors determining the onset of "chests" are mainly the site of operation, pre-existing respiratory infection, and sepsis, while close on their heels in the postoperative period comes immobility, whether the result of pain, morphine, or instructions from nurses and doctors. Wh active search for means of preventing "chests is not to be deprecated, too little attention is st paid to the treatment which is so important in t first day or two after operation if extensive atelectas is to be avoided. "Freedom of the bed" is t right of every patient who has had an operatio notwithstanding a possible reluctance of the nursi staff to give up the old-established back-rest a their aversion to the natural resting position—t horizontal.

Perhaps we could well dispense with a litt modernity in the anæsthetic room in exchange for little more in the ward. Let us have fewer respir tory depressions, apnœas, inflations, resuscitati injections, and even a little less of that hatred ether which is coupled with a love of anything els Let us encourage the patient to move about in be and to cough, and impress on nurses the presen day concepts of atelectasis. Lastly, let us aim a uniform accuracy in reporting pulmonary as we as other operative complications, whether in writin or discussion, so that new anæsthetic agents an methods can be properly assessed, at any rate wit regard to their effects on the chest, for the sake of thos who depend for guidance on the words of the elect.

Cineplastic and Krukenberg Amputations

THE unused muscle bellies in amputation stumps arm and forearm have long challenged the ingenuit of surgeons; nor has the design of upper-limb prosthese yet advanced far enough to discourage attempts t utilise the power buried in these stumps. Of th mechanical hands that have been devised and adopte in this country and in the United States, those Simpson and Hobbs, and the Norden hand whic contains a free-wheeling device and may be describe as a prosthesis within a prosthesis,[1] all give a grip an a greater range of function than is possible with an single adjustable appliance, but their mechanica function is limited, and they are cosmetically crude The appearance of upper-limb prostheses has no received the attention it deserves. From this point o view the acrylic hand constructed at the Walter Reed Hospital and the 'Vultex' hand described by Clarke,[2] of Baltimore, are probably the best. The magnitude of the problem can be judged from the number of casualties submitted to amputation. As a legacy of the late war, some 15,000 British Servicemen have amputation stumps, about a quarter of these being upper-limb amputations and a little over 5% double amputations, whereas in the first world war there were over 40,000 British soldiers with amputations. This difference roughly corresponds to the ratio between the total casualties in the two wars.

Up to the end of 1945 the Allied medical services had made little use of cineplastic amputations. Few, if any, were done in Britain, but Rank and Henderson [3] practised the method successfully in Australia, and the operation had been done several times at the United States Navy hospitals at Mare Island and Philadelphia. The earliest attempts to harness the

muscle power of amputation stumps, by passing skin-lined tubes through them, were made in Italy, but the cineplastic operation owes its full development to Prof. Ferdinand Sauerbruch, who introduced the use of big, well-buried skin-tubes of local tissue. Visitors to the Putti Institute at Bologna will remember the reversed abdominal tube pedicle which was made to provide the skin tunnel in forearm stumps. Since 1918 over 7000 cineplastic amputations have been performed at Sauerbruch's clinic at the Charité Krankenhaus in Berlin, and over 500 in the clinic of Prof. Max Lesche in Munich. Few aspects of German surgery have attracted more attention from Allied surgeons since VE-day, and both parties and individuals have paid many visits to Berlin and Munich to see this work. On another page Major Magee describes the cineplastic amputation as it is done in Berlin, where a local flap of skin, subcutaneous tissue, and deep fascia about 2 in. square is used to form the skin tunnel and the secondary defect is covered, not always completely, by a skin-graft. The operation is done under local anæsthesia. Professor Lesche's skin-flap is larger, perhaps 3 in. by $3^{1}/_{2}$ in.; the muscle tunnel is at least $1^{1}/_{4}$ in. in diameter and lies deep to three-quarters of the diameter of the muscle; the skin and fat tube is rotated through 90° before being passed through the muscle tunnel, so the suture line is proximal and away from the pressure of the peg; and the secondary defect is completely covered by a free graft. Observers have appreciated the advantages of attention to such details.

A properly made skin-tube buried in the forearm muscles or in the triceps should give an excursion of 1–2 cm. to a peg about 7 mm. in diameter lying transversely in the tunnel, and should be capable of exerting a power of 15–20 lb.; when buried in the biceps or in the pectoralis major the excursion of the peg should be 5 cm. or more and the power over 40 lb. This power is used to give grip to an artificial hand. Extension of the digits can be provided by a spring device in the prosthesis or by a skin tunnel through the extensor muscles which give voluntary movement—according to the choice of the surgeon. Cineplastic prostheses are fitted with blocking devices which allow the grip to be maintained without continuous muscular effort. The essential for success in the cineplastic method is prosthetic services of the highest order. Each of these cases is an individual problem, and successful function will depend largely on the skill and experience of the limb-maker. Surgery of this kind, except with close coöperation between surgeon and limb-maker, is useless. When properly made the cineplastic prosthesis has a fairly wide range of function—writing, use of cutlery or tools, and driving. This range is wider than that of any *single* appliance which can be fitted to a standard prosthesis. The advantage of the cineplastic amputation over the adjustable appliances is the great one of convenience; but most observers agree that neither the range nor the quality of function is as good as a well-trained patient can attain with the set of adjustable appliances in standard use in Britain.

In the Krukenberg forearm amputation, a pincers-like grip is provided by splitting the stump through the interosseous membrane between radius and ulna. The value of this amputation for African natives, who either could not obtain or would not use a modern prosthesis, was emphasised by Purce [4] and Squires.[5] Such circumstances remain one of the chief indications for the amputation, but German experience suggests that there are others. At operation, the cleft between radius and ulna is usually deepened to 12 cm., or at least a third of the length of the stump, and is so cut that there is local skin to cover either the ulna or the radius; as a rule, cover for the denuded side is provided by a free graft, but Professor Herlyn at Göttingen uses a belly-arm flap and incorporates an excess of abdominal skin at the depth of the cleft to ensure that there is a fold of flap here, not a suture line. In cutting the cleft, care is taken to preserve the pronator teres, since it is the action of pronation which approximates the two limbs of the pincers. In the cases observed at Göttingen by Fettes[6] these pincers gave a definite function to the limb, independent of prosthesis. Thus the patients could control a fork, perform their personal toilet, and use certain tools. None of the patients was concerned about the appearance of the lobster-claw-like stump. If necessary an ordinary upper-limb prosthesis can be fitted to the stump on occasion. The value of the Krukenberg amputation is limited, but it seems to be worth considering for men who have lost both upper limbs, and particularly for those who are also blind. It is these blind men who have lost both hands who make the greatest demands on surgical and medical ingenuity if their life is to be tolerable. For them a Krukenberg amputation, at least on one side, is worth considering because it can make them independent of a prosthesis and able to perform their own toilet.

In contrast to the end of the first world war, there has this time been remarkably little in any field of surgery for us to learn from Germany. Some aspects of amputation practice are possibly the sole exception. If the cineplastic and Krukenberg amputations developed by the German surgeons are to be given a trial here, it would be helpful if the limb-makers, and indeed some of the patients who have developed the maximum use of their stumps from clinics such as Lesche's or Sauerbruch's, would visit this country to give us the benefit of their experience.

A B C of the Act

The sections of the National Health Service Act to which its opponents object must by now be familiar to everyone. The able and persevering presentation of these objections has perhaps deflected some from studying the measure as a whole. For these and for others who would like to know more about the new service Mr. David Le Vay has written an account [1] which explains how it will affect citizen, patient, doctor, health worker, hospital, and local authority. Success, he says, will depend on two related factors—freedom from bureaucratic control and whole-hearted coöperation by the profession. The author emerges as a somewhat uncritical advocate of the service, but he has not allowed personal opinion to divert him from his principal aim, which is to explain its terms.

Annotations

CHRISTMAS IN THE MEDICAL FAMILY

DAILY bread is a fine thing, but much improved by butter; and if this year we must spread the butter rather thin it should help us to remember that in many countries today, and even in some homes in England, it is spread even thinner. The Royal Medical Benevolent Fund has a special concern with the butterless bread of one group of people at Christmas. Sir Arnold Lawson's letter[1] will have recalled to readers that the Fund tries to give a substantial Christmas present to medical men or their families who find themselves in need, and that last year it was possible to give a cheque of £4 to each recipient. He asks that this year the profession will make the same gift possible by sending the Fund £2000. Last year his appeal was exceeded by more than £100, and this year, they tell us, we all have more to spend and less to spend it on. Most doctors will gladly do a kindness if reminded. This is the reminder.

PARÆSTHESIÆ IN THE LEGS

PERVERTED sensations in the limbs—numbness, tingling, prickings, burnings, and so on—are a common symptom, and their causation in the hand has been clarified by the differentiation of the syndromes of costoclavicular compression and of lateral prolapse of cervical intervertebral disks. Similar symptoms in the legs and feet may be the manifestations of organic neurological diseases such as peripheral neuritis and subacute combined degeneration of the cord, or of deficiency of some factor of the vitamin-B complex, a condition often seen among prisoners-of-war and internees in the Far East[1]; but there are cases where the cause remains obscure. Ekhom[2] in Scandinavia, Allison[3] in Canada, and Martin[4] in London have drawn attention to paræsthesiæ in the feet and legs ("restless legs," or "leg jitters") which wake the sufferers at night and may keep recurring for years without signs of organic neurological or vascular disease developing.

Now Schepers[5] in Johannesburg has approached the problem afresh by studying 100 patients in an institution for chronic diseases who suffered from paræsthesiæ in the legs, and excluding cases of frank organic neurological disease or manifest psychoneurosis. There were five main groups among these cases. The largest group (47%) were suffering from organic diseases of the lower abdominal viscera—ureteritis associated with prostatitis or cervicitis, salpingo-oöphoritis, or chronic colitis. *In these patients there were areas of hyperæsthesia on* the thighs, lower part of the legs, and feet, the distribution to some extent depending on the abdominal condition. The explanation offered for the sensory disorder in these cases is either spread of inflammation to the lumbosacral plexus or involvement of the autonomic nerves and retrograde reflex irritation of spinal cord segments. The second main group (28%) were cases of macrocytic hyperchromic anæmia in which there was either impaired superficial sensation in the distal parts of the legs, thought to be due to degeneration of the termination of the peripheral nerves, or spread of the sensory impairment up the back of the thigh and buttock in the distribution of the sacral dermatomes. In this group Schepers suggests that ischæmia of the spinal cord plays a part in causation, and the paræsthesiæ always disappeared when the anæmia was corrected; it seems possible that they were early cases of subacute combined degeneration. In two groups, one associated with gravitational œdema (9%), often only slight, and the other with peripheral vascular spasm (4%), ischæmia of the nerve-endings was thought to the cause. Finally there were 12 cases of "maske hypothyroidism, in which scattered patches of hyp and hypo-æsthesia on the legs disappeared with adequ substitution therapy. Here the terminal parts of peripheral nerves were thought to be constricted they pierced the deep fascia, either because of increas turgidity in the nerves or because the fascia beca "fluid-logged" and rigid as a result of the endocri defect.

O AND ANTI-O

THE groups of human red blood cells are determin by the presence or absence of two specific antige A and B. Thus the four main blood-groups are A A, B, and O (i.e., zero, neither A nor B). Von Dunge and Hirszfeld[1] postulated that the inheritance of t A and B factors depended on two independent pairs allelic genes, A and a (not A) and B and b (not B But Bernstein[2] demonstrated mathematically that th view was not supported by statistical data, which di however, fit in with a theory assuming three allel genes—A, B, and O (or R), where A and B are domina over O. This theory has now been generally accepte It differs from that of von Dungern and Hirszfeld supposing that group O is determined by a positi antigen. The discovery of sera which will react wi group-O red cells has lent additional weight to Ber stein's hypothesis.

Twenty years ago Landsteiner and Levine[3] foun irregular iso-agglutinins in some rare human sera groups A_1B and A_1, which, though weak and acti only in the cold, would agglutinate red cells of grou A_2 and O. Since then more potent iso-sera have be *described in two persons of group* A_1[4, 5] *and two of* A_1B. In three of these four cases iso-immunisation by tran fusion or pregnancy may have increased the activi of the atypical iso-agglutinin, so that it became acti against the appropriate cells at body temperatu The serum of the latest example with *group* A_1 described this year by Henry, agglutinated not on O and A_2 red cells but also, though less strongly, son red cells of groups A_1, B, and A_2B.

Schiff[8] showed in 1927 that cattle sera sometim contained an agglutinin which would agglutinate huma group-O red cells. Eisler,[9] by immunisation wi Shiga bacilli, produced in goats an antibody which al would agglutinate group-O red cells. Both the natur ox sera and the immune goat sera agglutinate all huma red cells, but those of groups O and A_2 much more strongl than those of groups A_1, B, and A_1B. Furthermore, eve as some individuals of groups A and B secrete in the body fluids—notably the saliva and gastric juice—substances which have great A and B activity as measure by inhibition of anti-A and anti-B sera, so some individuals of group O secrete a substance capable c inhibiting anti-O sera.[10] Morgan and van Heyningen have noted that an even better source than saliva c A, B, and O active substances is the material fro pseudomucinous ovarian cysts. However, where "secretors" of A and B substances usually secrete i their saliva not only A or B but also O active *substanc* cyst fluid from A and B persons has not, except in on

instance, shown significant O activity. Morgan and Waddell,[12] using purified O active material from ovarian cysts, have immunised rabbits and obtained a serum with anti-O activity stronger than the natural anti-O serum obtained by selection from over 100 cattle sera. The titres against A_2 and O red cells of both this immune serum and of good ox serum were high; some B red cells reacted as strongly as A_2 red cells, and the reaction of A_1 red cells varied.

On the Bernstein theory, it might be expected that all heterozygous A and B red cells (i.e., AO and BO) would be agglutinated by powerful anti-O sera; but Hirszfeld and Amzel,[13] using a powerful immune goat serum as anti-O, could find no evidence of this. And Moureau[14] has reported a family AB x AB with 10 children—4 with AA, 2 with BB, and 4 with AB—in all of whom the red cells reacted with anti-O serum. Hirszfeld and Amzel regard the receptor O as almost ubiquitous in the human species and therefore almost a species factor (cf. Witebski and Okabe[15]). Matta[16] has rejected the theory that anti-O is a species antibody, since some AB, A, and B cells cannot completely absorb from a powerful anti-O serum all its anti-O activity, and anti-human sera do not agglutinate O cells more strongly than red cells of other groups. Wiener and Karowe[17] appear to accept the theory that anti-O is a species antibody, and attempt to explain diagrammatically why this serum reacts with O cells and heterozygous A_1, A_2, and B cells; but they do not explain its reactions with A_1A_1 and A_1B cells, which were found to be positive by Wiener.[18] Wiener explains this by comparing anti-O to anti-Hr′ (anti-c), and the O and A_2 agglutinogens to Hr′ antigens (c), which appear in the rh and Rh″, Rh_0, and Rh_2 genes of the Rh series—in other words, the genes contain a common antigen. The apparent presence of O antigen in Shiga bacilli, hog-gastric mucin, and probably other animal tissues excludes the possibility of its being a species-specific antigen. The bulk of evidence goes to show that it is almost universally present in human tissues but that it varies in quantity. It could be argued that it is a heterophile antigen. Eisler has shown that it is not the Foresman antigen, but it may be of similar type, originally universally present and still practically ubiquitous in human red cells, as described by Hirszfeld and Amzel. These workers describe a descending degree of reaction with anti-O serum, from O to A_5 to A_4 to A_3 to A_2 and to four grades of A_1 (A_m, A_r, A_j, and A_c), and a similar descending degree from O to B_2, B_m, B_r, and B_j: they postulate the presence of B_5, B_4, and B_3 at one end of the scale and B_c at the other. They suppose that in each case, by mutation through these stages, O is converted to A or B; thus, they argue, there is only a quantitative difference between the subgroups of A. Wiener[19] and Boorman et al.,[20] however, claim to have shown that there is a qualitative difference at least between A_2 and A_1, in that persons of group A_2 can have an anti-A_1 iso-agglutinin in the serum, capable of agglutinating in vitro and hæmolysing in vivo red cells of subgroup A_1.

It is possible to fit all the facts into a hypothesis which assumes that the O is a fundamental antigen, that the common A is a separate antigen, and that the A_1 antigen develops by mutation from O. Thus all A_2 and O cells would react strongly with anti-O, and A_1 red cells would react according to the degree of mutation of O to A_1. When mutation was complete, anti-O could appear in the serum of such a blood without infringing Landsteiner's law. A similar postulate would be needed for group B, although as yet no qualitative difference between human B antigens has been proved. Whatever the hypothesis favoured, there is sufficient evidence that the O antigen detected with these many anti-O sera differs from that of Bernstein's hypothesis. This does not disprove that hypothesis; it does, however, necessitate a revision of terminology, unless we revert to the use of R as the third antigen to A and B in Bernstein's hypothesis; but this might lead to confusion since the Rh antigen is sometimes known as R. Before new theories and terminologies are accepted it must be established that all these various anti-O sera have the same specificity.

MORE EXCITING GIVING

THE first proposals for the nationalisation of the hospitals under the new Act seemed to many to endanger much that was of value in the voluntary system. But the chairman at the annual meeting of King Edward's Hospital Fund for London last week, Lord Catto, said that the concessions made by the Minister in the process of transmuting the Bill into an Act have gone a long way to allay misgivings. Indeed he suggested that for the first time in the history of the hospitals it has become possible to give "without the mental reservation that the gift may be swallowed up in routine expenses."

The changes about to take place in the organisation of medicine will give scope to courageous pioneers, and the King's Fund are determined to make the most of their opportunities. Their influence is widening, for the abolition of the distinction between voluntary and municipal hospitals will allow them for the first time to help all the hospitals of London. Among the things on which the Fund propose to continue to spend money, Lord Catto mentioned the improvement of hospital catering, the recruitment of nurses and the provision of preliminary training schools for them, and the provision of special equipment and amenities. The Fund are also interesting themselves in accommodation for convalescents, and have lately appointed a committee which, with the Institute of Hospital Almoners, is surveying the needs and possibilities of these homes.

In proposing the vote of thanks to the chairman, Sir Herbert Eason, F.R.C.S., pointed out that the Fund during its existence had adapted itself to the varying needs of the voluntary hospitals, and he was confident that it would also adapt itself to the needs of the future.

TUBERCULOSIS IN NEWFOUNDLAND

IN July, 1945, the Newfoundland government invited Dr. T. O. Garland and Dr. D'Arcy Hart to investigate tuberculosis on the island. Their report[1] shows a serious state of affairs. About half the population of 320,000 live on the Avalon peninsula (including St. John's, the capital city of 50,000), while the rest live in tiny scattered settlements on the very long coastline. Radiographic surveys of samples indicate an average of about 3·5% of active cases of tuberculosis (adding previously known active cases to those newly discovered), but great variations were found in different places, suggesting local pockets or epidemics. Although the tuberculosis death-rate decreased from 236 per 100,000 in 1926 to 143 in 1943, it is still nearly three times that of Canada or Great Britain; in fact, Newfoundland is now where England and Wales were in 1910. The rate of decline in recent years has been approximately the same in the three countries, with the significant exception that in Newfoundland it started rising in 1932 and reached a peak in 1937, this rise coinciding with the years of severe economic depression. More women than men die of tuberculosis, which may be partly explained by their very hard life; besides housework, and perhaps minding the garden, they help with fishing, preparing baits, and mending nets.

The diet of many of the islanders is glaringly deficient in fresh fruit and vegetables, and in milk,[2] and could be improved by such means as home preparation of vitamin C from local berries, and by keeping goats for milk (cows are a rarity, and bovine tuberculosis does not play an important part). Houses are bad only in St. John's, but the general standard of living is low: in 1937 a third of the population was on relief and the allowances are wholly inadequate, sometimes "forcing a tuberculous household into the most abject poverty." It is suggested that special allowances be made to tuberculous patients and their families, and that industries should be obliged to take a proportion of those recovering from the disease. There is at present only one sanatorium for the whole island, and hospitals and dispensaries are needed. Training will be required for the doctors and nurses staffing these institutions, and Dr. Garland and Dr. Hart want to see more mass radiography, using the miniature film, and tuberculin-testing of children to act as a pointer to open cases.

LOUSE-BORNE TYPHUS

Complication and simplification seem to alternate in the classification of the typhus group of fevers. This statement applies equally to tick-borne, mite-borne, and louse-borne typhus.[1] Up to about forty years ago only one form of louse-borne typhus was recognised—that now called epidemic exanthematous typhus, caused by *Rickettsia prowazeki*, and conveyed by *Pediculus humanus*—but about that time Wolhynian fever, caused by *R. wolhynica*, was described as a specific entity in Poland. In the war of 1914–18 a third entity, trench fever or five-day fever, was recognised and attributed to *R. quintana*. In the interval between that war and 1939 very little was heard of trench fever; but a fourth form of louse-borne typhus, in laboratory workers, was described by Mosing,[2] who named the causal organism *R. weigli*. Weigl's prophylactic vaccine against typhus exanthematicus is prepared by injecting suspensions of *R. prowazeki* into lice per rectum and after an interval removing their intestines and grinding them up in formol-saline. For this method very large numbers of lice are needed and these have to be fed on laboratory workers; it was these workers who contracted the disease. A few years later, however, it was considered that *R. quintana* and *R. wolhynica*, the causal organisms of trench fever and wolhynian fever respectively, were identical, and that *R. weigli* was probably the same organism.

An outbreak similar to that described by Mosing took place at Addis Ababa in 1941–42, soon after the occupation by British troops. It involved seven laboratory workers engaged in feeding lice for Weigl's method of making prophylactic vaccine, and is described by Codeleoncini,[3] who details the isolation of a rickettsia from such cases, the laboratory findings, and experimental work on guineapigs and monkeys (*Papio doguerœ*), all of which convince him that trench fever, the disease described by Mosing, and the Ethiopian disease are identical and due to one and the same rickettsia, which is the common louse rickettsia, *R. pediculi*. Codeleoncini further suggests that the disease develops only when enormous numbers of lice are present—e.g., in trench warfare and in laboratory feeding of lice for making Weigl's vaccine—and that probably an endemic focus in Russia acts as a reservoir between outbreaks.

CAUSE OF NUTRITIONAL ŒDEMA

Nutritional œdema is usually thought to be d to hypoproteinæmia, especially a deficiency of serum-albumin, which normally maintains the osmotic pressure of the plasma, thus preventing the escape of fluid from the blood-stream. This view was put forward in 18 by Starling, who did not, however, postulate that hypoproteinæmia was the sole cause of the œdema Bayliss later showed that a second factor was a high venous pressure. When the hydrostatic pressure the venous capillaries is raised fluid filters from plasma through the vessel walls to swell the intercellu fluid of the tissues—e.g., in the œdema of chronic heart-failure.

There is yet a third possible cause of nutritiona œdema. Peters[1] has emphasised the importance of th cell membrane as a physiological boundary separa the cells and intracellular fluid from the intercellu fluid. Consequently it is imaginable that œdema c also be produced by leakage from intracellular to inter cellular fluid. This supposition is supported by Bachet, who found that 17 cases of early œdema among 120 of nutritional œdema had a normal serum-albumin level and estimations of serum-albumin in non-œdematou patients who subsequently developed œdema showed no hypoproteinæmia anticipating the œdema. Further, he found that signs of heart-failure were rare in the early stages of nutritional œdema. These findings militate against the theories that nutritional œdema is caused, in the first instance, by hypoproteinæmia or by high venous pressure though both of these mechanisms come into play in the later stages and increase the existing œdema. Bachet therefore argues that nutritional œdema starts in the cells, and that it is only later that the serum-albumin level falls—in other words, that nutritional œdema is due to an insufficiency of proteins in the diet, leading to a deficiency of albumin in the tissues. On the other hand, the occurrence of œdema with a normal serum-protein may be due to some factor which interferes with the function of the vascular endothelium—vitamin deficiencies, for example—rather than to actual protein lack within the cells. For the present the verdict on Bachet's hypothesis must be "not proven."

Lamy and his co-workers,[3] in a study of 38 prisoners-of-war, have confirmed the lack of correlation between serum-protein levels and œdema and have carried the investigation a step further. They measured the serum-protein levels and the osmotic pressure of the serum in 8 prisoners-of-war suffering from malnutrition, 2 with no œdema, 2 with slight malleolar œdema, and 4 with severe œdema, and found that a lowering of the osmotic pressure of the serum was clearly correlated with an increase in œdema, though the serum-protein level was normal in all cases. They conclude that the serum of the patients with œdema contains an abnormal protein of low osmotic pressure, and that this protein is derived from muscle. They do not, however, believe that the low osmotic pressure alone is responsible for the onset of œdema in malnutrition, and support the view that the main factor is an increased permeability of the capillary walls.

Sir William Collins, K.C.V.O., F.R.C.S., who died on Dec. 11 at the age of 87, will be remembered as the creator of the London Ambulance Service. As chairman of the London County Council, as Member of Parliament, and as ophthalmic surgeon to several London hospitals, he served medicine both inside and outside his profession. He was also British plenipotentiary at conferences on the control of dangerous drugs.

RESPONSIBILITY FOR THE "CHRONIC" SICK

THE HISTORICAL PERSPECTIVE

A. G. L. IVES
M.V.O., M.A. Oxfd

ONE sometimes hears it said that the voluntary hospitals have failed in their duty to the incurable or chronic case, and the inference is drawn that one of the achievements of the National Health Service Act will be to return them to their original wider purposes by bringing all the sick—acute and chronic alike—under a single administration. Since we are on the eve of one of the greatest changes in hospital history in this country, it may be of interest, and possibly of some value in adjustment of perspective, to inquire to what extent this is true. In part at least it represents a modification of the facts of history to suit our present outlook.

FUNCTION OF HOSPITALS

Let us attempt a very brief résumé of the past history of the function of the hospitals. The story falls into three main phases.

The hospitals of pre-Reformation days, of which St. Bartholomew's and St. Thomas's are our only two remaining examples, certainly accepted a very wide interpretation of their duty, in common with most other medieval hospitals. The earliest hospital appeal of which we have record is that which followed the fire that destroyed St. Thomas's in 1215. "Behold at Southwark an ancient hospital built of old to entertain the poor. . . ." "To entertain the poor"—the phrase reflects admirably the wide scope of the word "hospital"—it extended even to the destitute.

After the dissolution of the monasteries and the refoundation in the 16th century of St. Bartholomew's and St. Thomas's this conception was in practice modified though not abandoned. The citizens of London made a careful census of those for whom they wished to provide, as follows: fatherless children 300; children overburdening their parents 350; sick and lame persons 200; aged and infirm 400; poor householders 600; idle vagabonds 200. Christ's Hospital was to take care of the children, while Bridewell took charge of the idle, and Bedlam the insane. St. Bartholomew's and St. Thomas's between them cared for the remainder, curable and incurable alike. The churches, streets, and lanes were daily filled with "sick and infirm poor men lying begging." It was the fact that the refounded St. Bartholomew's could not receive a tenth of them that inspired Bishop Ridley to urge upon Edward VI the propriety of refounding "the late hospital of Thomas Becket in Southwark." In the refounded St. Thomas's there was for many years a "night lodgers' ward" into which the hospitaller admitted such cases as he deemed deserving. The poor were put to "such convenient occupations as they are most apt unto." But in the century and a half between 1552 and 1700 the two hospitals carried between them the whole burden of caring for the sick of London, and the pressure upon their resources was such that the incurable had to give way to the curable. The abstract of orders for St. Thomas's for the year 1700 *specifically records* "*No incurables are to be received.*"

A few years later Thomas Guy recognised the need for provision for those excluded from the two royal hospitals, but he had doubts about the practicability of his purpose. The wording is illuminating, and discloses very plainly the nature of the dilemma: it explains and justifies the action of the royal hospitals. Within a few years of his death the governors republished the words of his will, and pointed out that people had generally understood by it such as "laboured under distempers, loss of limbs, blindness, and other natural and accidental infirmities, and even age itself." If taken in such a sense it would soon have become an almshouse; he had accordingly described the persons for whom his hospital was intended—"to be such as were capable of relief by Physick and Surgery." Guy's thus came into line with the other two hospitals.

The voluntary hospitals of the 18th century followed suit. The Westminster Hospital limited the stay to a month, and excluded incurables. The London Hospital was for "relieving the poor in case of sickness or accident." A similar view was taken at Edinburgh; though the records are not explicit, the implications are clear enough. And so with the others. It is a mistake to suppose that the voluntary hospitals of the 18th century were founded with a wide all-embracing purpose, and that their malign successors have gradually excluded the incurables. The object of the restriction was to prevent abuse of their facilities; otherwise they would have become almshouses rather than hospitals.

UNDER THE POOR-LAW

The provision of inpatient accommodation under the poor-law dates from 1723, when an Act was passed empowering parishes to unite in "unions" for the purpose of building workhouses. In them were usually provided quarters for inmates who fell sick, but the intention was that those who seriously required medical treatment should "if possible" be removed to a hospital. By 1864 the neglect in the workhouses had become a scandal, as the famous investigation by THE LANCET showed—"a mere similacrum of real hospital accommodation."

Three years later the Act of 1867 established the Metropolitan Asylums Board and made provision for poor-law infirmaries absolutely separate from the workhouse. Thirty years later conditions were still such as to earn the vigorous condemnation of Sir Henry Burdett, though the scale of the provision made had been vastly *increased*.

Legislation permitting, but not requiring, local authorities to provide general hospitals besides hospitals for infectious diseases under public-health powers goes back to the Public Health Act of 1878. But as late as 1929 Bradford was the only county borough which *exercised these* powers. Administrative convenience was all on the side of provision by way of the poor-law. The Act of 1929 confirmed the option, giving local authorities in terms the right, though not the duty, to provide hospital accommodation under public-health powers; but by the beginning of 1937 only 36 county *boroughs had* exercised their option, and many still today make this provision under public-assistance rather *than public-health* powers.

In 1928 Sir George Newman, in his annual report, spoke of the "clear direction" given that the process "known for the last twenty years as the break-up of the Poor Law should be put in hand in a practical manner." But the fact is that there is no formal obligation upon anyone to provide for the incurable unless they be also destitute and fall under the poor-law.

UNDER THE NATIONAL HEALTH SERVICE ACT

The new Act changes this; it becomes the responsibility of the Minister to provide "to such extent as he considers necessary to meet reasonable requirements . . . hospital accommodation." "Hospital" is defined as meaning an institution for the reception and treatment of persons suffering from illness, and "illness" in turn includes any injury or *disability* requiring medical treatment or nursing.

This brief survey of hospital history may serve to correct an impression which seems to be gaining ground that the voluntary hospitals have neglected their clear duty in regard to the "incurable" side of hospital work.

To substantiate the contention one has to go back many years before the foundation of the vast majority of the voluntary hospitals in the 18th and 19th centuries, and reinterpret the very word " hospital "—to give it, in fact, a medieval connotation. That is what the present Act really does; and it is all to the good. But to be fully in line with the early meaning of the word it would be necessary to go much further still, and to include within the ambit of the hospital services not only all suffering from illness that require medical or nursing care but also all the poor and necessitous. Maybe one day we shall, and the hospital will become once again a place " to entertain the poor," and care, rather than cure, become the accepted translation of *cura*.

YES OR NO ?

RESULTS OF B.M.A. PLEBISCITE

THE British Medical Association on Nov. 15 sent the following question to 56,671 members of the medical profession: " Do you desire the Negotiating Committee to enter into discussions with the Minister on the regulations authorised by the National Health Service Act ? "

By Monday last 38,872 replies had been received from civilians, of which 17,688 (45·5%) were Yes and 21,184 (54·5%) were No. Of the 34% of Service doctors whose replies had been received by Monday, 56% voted Yes and 44% No.

In view of the special difficulties attending the Service poll, Service voters will be given until Jan. 6 to record their votes. A final report on the plebiscite, embodying civilian and Service figures, will be made soon after that date. Meanwhile the accompanying tables give figures up till Dec. 16.

STATEMENT BY DR. DAIN

On Dec. 12, explaining the decision of the B.M.A. council, Dr. GUY DAIN, the chairman, said that " the medical profession has stated plainly through its Negotiating Committee that the National Health Service Act as passed is in conflict with the principles of the profession." Having received the results of the plebiscite, the council had had to consider whether there was a majority and, if so, whether this was sufficient to justify not entering into discussions with the Minister. Its answer to both questions was in the affirmative. It had decided to call a special meeting of the representative body of the association on Jan. 28 to consider the resu of the plebiscite and to approve the following resolutio

> " That the Negotiating Committee be advised th in view of the results of the plebiscite the Minister informed that because of the divergence between t principles of the profession and the provisions of t National Health Service Act, the committee is unal to enter into discussions with the Minister on t regulations to be made under that Act."

Examination of the results showed that of the docto mainly concerned—i.e., the general practitioners 64% had voted against negotiating. As was to expected, this situation was reversed in the case of m already in whole-time salaried appointments, though t large proportion of those actually in Government servi voting against negotiation was regarded as significa The poll of civilian doctors was just over 80%— extraordinary response comparing more than favourabl for example, with the poll at the last two Gener Elections. The Service poll was inevitably small, account of distance and difficulty of tracing units, on 32% replies being received at the time of speakin Examination of the analysis showed a consistent pictur " in the general practitioner group the young docto

effectively support the majority against negotiation. There is no question of age overweighting the decision."

"The B.M.A.," Dr. Dain continued, "is a democratic body and in the light of these figures the council has no mandate to negotiate. The position therefore is that the B.M.A. is not empowered to accept any invitation that may be given by the Minister to the medical profession to join him in discussing the regulations to be made under the National Health Service Act. He may have many offers of help, but none from the main body representing the profession.

"It is important to remember that the National Health Service Act is not a Conscription Act and that a decision not to join the service is not disloyalty to the country. Whatever the ultimate outcome the doctors will be loyal to their calling and to their patients to whom, as always, they owe their first duty."

In answer to questions from the press, Dr. Dain stated that in reaching its decision the council had been influenced by the high negative vote among general practitioners and their assistants. Whether the B.M.A.'s withdrawal would mean the end of the Act was for the Minister to decide. The Act could not be carried out with 55% of the profession withholding their services, and even if 100% were in favour they would not be able to work it in its present form. He saw no way out except an amending Act.

Dr. CHARLES HILL, secretary of the B.M.A., explained that the profession would go on doing its work: "there is no strike here; no question of pay or conditions of service arise." As quoted in the *Manchester Guardian* (Dec. 13) he added:

> "We believe in a comprehensive service available to all who need it; we believe in the merging of municipal and voluntary hospital services; we believe in the regionalisation of hospital services."

It would be necessary, he said, for the profession to make its proposals towards these ends.

THE MINISTER'S COMMENT

After the announcement of the result of the plebiscite the following statement was issued by the Ministry of Health:

> "The Minister has learnt that the B.M.A. are placing the results of the plebiscite before a special representative meeting with a recommendation that the profession should refuse to discuss with him the steps to be taken to bring the National Health Service Act into operation. He hopes that before any final decision is taken accepting this recommendation, wiser counsels will have prevailed; and he feels sure that the medical profession will take no steps which would make it difficult for them to take part in the comprehensive health service which the people of this country so ardently desire.
>
> "Meanwhile, the Minister has a clear duty to carry out the instructions of Parliament as expressed in the Act, and he can no longer postpone the consultations which are a necessary preliminary to the setting up of the administrative machinery. He is, therefore, proceeding to consult all the many other interests which will be concerned in the National Health Service. He is also considering what ought to be done—and this is a matter to which he attaches great importance—to give the medical profession the opportunity of assisting to shape, and of playing its part in, the new service."

TRADE-UNION MEMBERSHIP

THE following letter, signed by Dr. Charles Hill as secretary, is being sent by the British Medical Association to all local authorities:

> The Association has considered, with particular reference to medical officers in the local government service, the position arising from the repeal by the Trade Disputes and Trade Unions Act, 1946, of the Trade Disputes and Trade Unions Act, 1927, Section 6 of which made it illegal for any local or other public body to require as a condition of the employment of any person that he should or should not be a member of a trade union.
>
> Some local authorities have passed resolutions imposing on their employees a requirement of membership of a trade union or other organisation. In this connection I am instructed to inform you that the British Medical Association, which represents the great majority of doctors and enjoys a membership of over 54,000 and is the negotiating body for the medical profession, recognised as such by the Ministry of Health and the associations of local authorities, is opposed on principle to a practitioner being required to join any body, British Medical Association or other—this does not of course apply to membership of medical defence societies. The Association prefers that its membership should be voluntary, the strength of the Association remaining an expression of the profession's confidence in its representative body.

I should be glad to hear from you on this matter with regard to appointments under your Authority.

On Dec. 11 the council of the B.M.A. decided that—

> Where an authority imposes upon its officers or candidates for office a requirement of a membership of a particular body or bodies, B.M.A. or other (but excluding medical defence societies), the Association should protest to such authority, and afford financial help to any practitioner who suffers as a result of accepting the advice of the Association. All advertisements for whole-time public health medical officer appointments of such authorities, submitted by such authorities for publication in the *British Medical Journal*, shall be rejected and the profession advised not to make applications for such posts.

DEVELOPMENT OF NEUROSURGERY

REVIEW BY MR. CALVERT

WITH Prof. W. W. D. THOMSON in the chair, the annual address to medical students of the Royal Victoria Hospital, Belfast, at the opening of the winter session, was given by Mr. C. A. CALVERT, F.R.C.S.I., who spoke on the history and development of neurosurgery.

Though neurosurgery is one of the most youthful of the surgical specialties, surgery of the skull was, he said, one of the earliest crafts. In the Edwin Smith papyrus, of about the 16th century B.C., 27 cases of head injury are described, and the occurrence of deafness in fracture of the temporal bone is noted, together with the advice that in closed head injuries decompression should be performed at the point of contusion. Hippocrates emphasised that no head injury was to be considered trifling, since even a scalp wound might prove fatal. His classification of skull fractures was almost modern, and he advised the use of a trephine in certain cases and that, when the instrument becomes hot, it should be cooled from time to time, the greatest care being taken to avoid injury to the dura. His subsequent dressing, a preparation of either wine and honey or of tar, was virtually an antiseptic application.

Under the Romans surgical operations were carried out for many different conditions, and the surgeons were equipped with many well-constructed instruments. Some of Celsus's observations on head injuries included the serious prognostic significance of prolonged unconsciousness and bleeding from the nose and ears. Galen, unfortunately, said that surgery was to be regarded merely as a branch of medicine, and this was interpreted by the Arabs (to whom is due the credit for preserving many of the works of the ancient Greeks) as meaning that surgery is an inferior kind of work. As a result, in medieval times physicians came to regard any method of treatment which involved the shedding of blood as being beneath their dignity.

After Vesalius's publication of his treatise on human anatomy the spirit of investigation once more stirred abroad, and the great French military surgeon of the 16th century, Ambroise Paré, introduced a rational attitude in the treatment of wounds. In 1760 Percival Pott published an important treatise on head injuries and gave an admirable account of extradural abscess. Instead of using the cruciate incision of the ancients, Pott exposed the skull by cutting out a complete circle of scalp, and he divided skull fractures simply into those with, and those without, depression, his practice being to operate on all cases of depressed fracture. But though Pott added considerably to our knowledge of head injuries, and men like himself and Cheselden did much to improve craftsmanship, no new principle was introduced into surgery from the time of Ambroise Paré until the advent of John Hunter towards the close of the 18th century.

During the first half of the 19th century surgical technique had developed to a state that could scarcely be excelled, but anæsthetics were still not available until Morton, in America, introduced ether in 1842 and Simpson, of Edinburgh, discovered chloroform in 1847. Even then the spectre of postoperative sepsis precluded any widening of the application of surgery, and operation on the body cavities was not attempted until 1867, when Lister introduced the principle of the antiseptic treatment of wounds. By this time knowledge of diseases of the nervous system had already been considerably advanced.

In 1862 Broca discovered that the posterior end of third left frontal convolution was the centre for articulate speech in right-handed persons. He was the first to trephine for cerebral abscess, the situation of which could now be defined by his theory of cortical localisation. In the latter half of the 19th century neurologists unravelled the syndromes of neurological disorders and built up, with the experimental physiologists, pathologists, and others, the foundations of modern neurosurgery. The first removal of a cerebral tumour was carried out in 1884 by Mr. Rickman Godlee, but the pathology and life-history of tumours was not fully understood, and the hydrostatic factors which complicated space-occupying lesions within the skull had still to be learnt by bitter experience.

In the last two decades of the 19th century knowledge of cerebral localisation increased immeasurably. Horsley may be said to have established the surgery of the central nervous system on a scientific basis. He standardised the methods of operative approach for brain and spinal-cord tumours, and was one of the first to realise that vision could be preserved, headache relieved, and life prolonged by decompression. Working in association with Gowers, he carried out the first successful removal of a spinal-cord tumour in 1887. One of the fields in which encouraging results were first recorded was in the treatment of intracerebral abscess. Sir William Macewen's classical work on the subject was published in 1893; of 20 cases on which he had operated all except two recovered. These results have not been surpassed, or perhaps even equalled, up to the present day.

In the opening years of the present century Harvey Cushing, in America, gradually built up a school of neurosurgery. There was a steady flow of new ideas from his clinic. The physiology of the pituitary was worked out by Cushing, and the enlargements to which it was subject were clearly defined.

At one time all tumours arising within the brain were lumped together as sarcomas. Neuropathologists demonstrated that these tumours arise from the supporting cells of the brain in the glia, and they renamed them gliomata. Recognition of their varying degree of malignancy and rate of growth helped greatly in directing the neurosurgeon when to stay his hand and when to try and effect a complete removal.

The diagnostic value of X rays was not utilised to the full in neurosurgery until after 1918, when Dandy demonstrated that air could be used as a contrast medium to outline the ventricular system, thus providing a method whereby not only the situation but also the size of most brain tumours could be determined. Another new form of radiological investigation was that of cerebral arteriography. A contribution of signal value was the adoption of the high-frequency current for the coagulation and excision of intracranial tumours by Cushing and Bovie in 1926. Diathermy served a dual purpose: it reduced the incidence of bleeding and paved the way for extirpation of many tumours whose removal previously had to be abandoned because of difficulties of access. Two very recent additions to our operative resources are substances prepared by the fractionation of human blood-plasma and named fibrin-foam and fibrin-film by their originators, Ingraham and Bailey, of Boston. The foam is of immense value as a hæmostatic agent, and the film provides an excellent dural substitute. Also great advances were made in overcoming sepsis by the introduction of the sulphonamides and penicillin. In the 1914–18 war the death-rate from wounds in which the dura had been penetrated was 55–60%, though Cushing, in his final series of selected cases, reduced the mortality to 28·8%. In the war of 1939–45 the death-rate from all forms of penetrating wounds of the brain, transventricular cases included, was about 8·9%.

Finally, Mr. Calvert said, neurosurgeons have had the temerity to invade the territory of the psychiatrist. Though the range of application of frontal leucotomy, originally devised by Moniz and Lima, and precise knowledge of the tracts in the brain to which section should be restricted still await accurate definition, many hundreds of leucotomies have been performed, and the results indicate the undoubted merit of the procedure in carefully selected cases.

Reconstruction

HOSPITALS

REGIONAL SURVEY OF NORTH-EAST

THE last of the hospital surveys,[1] dealing with the north-eastern area, which has now been published, is of the same high quality as earlier volumes in the series. The area includes two counties (Durham and Northumberland) and part of a third (North Riding of Yorkshire), eight county boroughs (Newcastle, Tynemouth, Darlington, Gateshead, South Shields, Sunderland, West Hartlepool, and Middlesbrough), and 81 minor authorities. The population exceeds two and a half million, served by 112 local-authority and 54 voluntary hospitals, with 11,634 and 4490 beds respectively. The survey area is coterminous with the region of influence of the Newcastle school of medicine, which should, in addition, extend to Carlisle and Cumberland, and a small area of Yorkshire around Whitby.

HOSPITAL BEDS

The surveyors follow the usual plan of dealing seriatim with the various kinds of hospital services—acute sick, chronic sick, accident services, ambulances, &c.—and then considering the facilities provided by each hospital, grouped into natural hospital districts; five of these are recommended, based on large towns which are social and business centres, but ignoring local-government boundaries. The surveyors comment on the interest of hospital managing bodies and of local doctors in the future of the hospitals, and their recognition that the services are not at present meeting all needs.

For the acute sick there should be more beds, more consultants (these, as elsewhere, can at present earn a living only in the teaching centre), and more up-to-date buildings; despite housing and school priorities, some new hospital building is urgently necessary. In the meantime, consultants should be trained. The general hospitals in which the acute sick are treated are classified into three main groups:

(1) The *teaching hospital* at Newcastle, the Royal Victoria Infirmary, which, with the municipal general hospital and the special hospitals, should form a centre whose influence and example would be felt throughout the region.

(2) *District* or *main hospitals* of 600–800 beds (some of which would be formed by combining several existing hospitals) which should be fully staffed by consultants, responsible for the treatment of both in- and out-patients.

(3) *Cottage hospitals*, which fulfil a useful purpose within their proper sphere. They are essentially general-practitioner hospitals, and, while they need some out-patient facilities, they should not retain patients needing special investigation and treatment.

The chronic sick, here as elsewhere, receive insufficient provision, both medical and social. Full investigation and any treatment should be available in large general hospitals before their admission to other institutions. Consultants should regularly visit the wards and institutions containing the chronic sick, among whom there is a large field for clinical research.

The accident services in an area of heavy industry such as this are already good in many places—the Victoria Infirmary probably treats more fractures than any other English general hospital—but further expansion of both accommodation and expert staff are needed in some parts. Rehabilitation should be available in every orthopædic department, special rehabilitation centres should be provided for long-stay inpatients, and each hospital district should have its own accident service. The ambulance services should be more closely coördinated, preferably on the basis of hospital districts; each of these should have a central bureau which would be available day and night.

SPECIAL SERVICES

For the orthopædic service the surveyors recommend the integration of an expanded service organised in three sections, for Northumberland, Durham, and the North Riding. The tuberculosis service, with 2146 beds, also requires some expansion, partly because more cases are recognised as needing treatment and partly because of the conditions imposed by modern therapy. Any accommodation which ultimately proves surplus to this particular work will be invaluable as a country open-air hospital. The tuberculosis service should be more closely associated with that of the general hospitals: closer attention, for the sake of both patients and staff, should be given to the kind of accommodation provided for advanced cases; and a better service would result from the grouping of authorities.

The surveyors hold the same opinions on the future provision of infectious-disease accommodation as their colleagues of other regions. The community-value of isolating these diseases is secondary to the advantage the patients can derive from expert treatment in large units. The existing 49 fever hospitals (with 2649 beds) should as a first step be reduced to 17 (with 1973 beds); but the apparent 34% loss of beds would be largely compensated by the increased provision of cubicle blocks, allowing of the easy treatment of different diseases in the same block with a minimal risk of cross-infection. The final concentration should be into 6 or so large hospitals; and in the meantime, infectious-disease units at general hospitals should be developed on an experimental basis. Smallpox, whose infectiousness still demands circumspection, may at present still be allotted to 16 hospitals, some of which are fit only for permanent closure. The use of specially built and isolated blocks inside the curtilage of large fever hospitals merits consideration, and one or two of the best fever hospitals to be disused should be kept in reserve to meet emergencies.

While the surveyors disagree on the desirable total of maternity beds, they are at one in recommending that the 434 beds available for a proportion of the 45,000 annual births should be supplemented by at least a further 200. Many, for normal deliveries, should be in small units, but all should be linked, on the basis of hospital districts, with the principal maternity hospital.

In the section on pædiatric services, the appointment of a professor of child health at Newcastle in 1942 is commended, and his importance in the training of future pædiatricians emphasised.

The North of England Joint Cancer Committee was formed in 1945, and covers not only the greater part of the survey area but also Cumberland and Carlisle. Investigation and follow-up are centred on the Newcastle hospitals; the central bureau is at the Victoria Infirmary, and non-surgical cases are mainly dealt with in the cancer unit at Shotley Bridge Emergency Hospital. Other approved hospitals will come into the scheme as associated hospitals; a cancer unit will be established at Cumberland Infirmary and joint consultation between clinician and radiotherapist to decide appropriate treatment is an accepted principle.

As elsewhere, existing pathological services need augmentation; pathologists, technicians, and laboratories are insufficient for the work which should be done. But in this field, as in many others, the needs of the region have already been considered at the instigation of the North-eastern Hospitals Regional Council. Durham, Newcastle, Gateshead, and Tynemouth have already agreed to establish a joint committee to take over the management of the university and city laboratories, and to coördinate the work with that of the Northumberland county laboratory; the nucleus of an authoritative epidemiological centre will thus be established. There should be association of the laboratories at South Shields and the Hartlepools with that at the Sunderland Royal Infirmary. There is also need for a pathological institute at Middlesbrough, and laboratories at Darlington and Durham.

NURSES

Here, as elsewhere, the demand for nurses exceeds the supply; but even before the war insufficient nurses were appointed for the number of hospital patients. This must be rectified, and the necessary increase in hospital and sanatorium beds will intensify the problem. Encouragement can be drawn from the fact that between 1936 and 1944 the number of nurses entering for the preliminary State examination increased by 75%; but wastage during the training period amounted to over 50%, so that the number qualifying increased by only 34%. The awkward gap between school-leaving age and the age of entry for nursing training may be partly surmounted by the introduction of preliminary courses in secondary and technical schools; 14 such schools have been approved in the north-eastern area. For the rest, the establishment of preliminary training schools and of the State roll of assistant nurses are steps in the right direction.

---

[1] Hospital Survey: the Hospital Services of the North-eastern Area. By Sir Hugh Lett, Bt., C.B.E., D.C.L., F.R.C.S.; and A. E. Quine, M.B., F.R.C.S., D.P.H. H.M. Stationery Office. 1946. Pp.

DISTRICT ORGANISATION

The surveyors recommend the organisation of the hospitals in the region on the basis of five hospital districts.

(1) *Newcastle,* with a population of almost 1¼ million, to include Northumberland, part of Durham, and the associated county boroughs. There is a general need for more beds and a particular need for more medical beds in Newcastle itself even when Durham's services are fully developed. The hospitals should have as their focusing-point a hospital centre in Newcastle, to include the Royal Infirmary and six of the special hospitals. When this becomes possible, a further 350 beds, to bring the total to 1250, will be needed, as well as more consultants, who should also be on the staffs of other hospitals. Other needs in this district are enlargements at Gateshead, a new hospital at Bedlington-Ashington, more maternity units, and more and better accommodation for the chronic sick. The local application of the surveyors' infectious-disease concentration policy is specified in this and the other districts.

(2) The *Sunderland district* has a population of nearly 360,000 and needs more acute beds (to be provided by additions to existing units), more consultants, and more maternity units.

(3) The *Middlesbrough district* also has a population of about 360,000; and a large new general hospital of not less than 800 beds is needed in Middlesbrough itself.

(4) The *Darlington district,* with a population of 170,000, should have the size of its municipal hospital almost doubled.

(5) The *Durham district,* with its 288,000 population, has mainly relied on Newcastle for its hospital services, and is short of indigenous facilities, which should be established round a new hospital at Dryburn and the Durham County Hospital.

In addition to these five districts, the surveyors give some consideration to the Hartlepools, where, at the time that their report was written, local considerations might have necessitated the development of a hospital service for the 120,000 people living in the area. In view of the proposals in the National Health Service Bill, however, the services in this area will probably develop in association with those of either the Sunderland or Middlesbrough district.

This report reflects the coöperation between all hospital services, municipal and voluntary, which has steadily developed in this region. This is further illustrated in the report for 1945 of the North-eastern Hospitals Regional Advisory Council which, under the active chairmanship of Lord Eustace Percy, has outlined development plans which should be of great use for the future. The pathological and accident services, maternity-bed provision, the hospital centre for Newcastle, the requirements of an outpatient polyclinic, and various other matters have been fully explored by special committees and subcommittees of the council.

"... It is easier to build a new hospital at the cost of a million pounds than to make sure that old-fashioned methods of treatment and nursing are not preserved inside those new walls."—Dr. HARLEY WILLIAMS in *Doctors Differ,* London, 1946, p. 99.

In England Now

A Running Commentary by Peripatetic Correspondent

THE psychiatrists have had a go—in fact a good man goes—at Hitler. It is time the neurologists had a chan and here are some data for them which are at any rat more concrete than the speculations on which th psychiatrists have based their diagnoses from a distance.

Mr. H. R. Trevor-Roper, writing about Hitler in th *Daily Telegraph* on Nov. 29, says: "In 1943 the firs symptoms of physical alteration became apparent Hitler's extremities began to tremble, especially the lef arm and the left leg, his left foot dragged upon th ground; and he developed a stoop. The tremor was not as has often been stated, a consequence of the explosio of July 20, 1944, it had already been obvious for som time, and the visible decline of the Fuehrer's health ha even been the subject of an emotional broadcast b Dr. Goebbels in April, 1943. . . . All witnesses of the fina days agree when they describe his emaciated face, hi grey complexion, his stooping body, his shaking hand and foot, his hoarse and quavering voice, and the film of exhaustion that covered his eyes." Now these allowing for the fact that they are the observations o laymen, are a remarkably accurate account of th symptoms of parkinsonism. Moreover, Mr. Trevor-Rope records that Hitler was being given a preparation containing belladonna, of which he took two to four pills with every meal. Mr. Trevor-Roper takes the view that Hitler's symptoms were due to the variety of drugs which he was given, but if Hitler had parkinsonism belladonna was the appropriate remedy. There must still be enough witnesses, perhaps even medical witnesses, to clear up the point.

If indeed Hitler had parkinsonism, was it due to encephalitis lethargica? And was his illness in 1918, when his eyes were affected, not hysterical at all but the initial attack of acute encephalitis which was epidemic at that time? If so, was this disease responsible for his aggressive temperament and all that followed from it, and also for his final downfall? Has the history of Europe in the last twenty-five years been merely a commentary on the activities of a neurotropic virus in one man's brain?

* * *

Wives of G.P.s with a char for two hours a day, a child of four, and a consulting-room in the house will anticipate what I mean when I say that it has been one of those days.

It was 7 P.M. with a gale howling when my husband was called out for the fourth time and 7.15 when the door bell chimed. A man stood on the step with his left hand swathed in a handkerchief. Poor devil, I thought, another injured hand. I was prepared to do my stuff. He glared at me and shouted angrily, "What have you done to your gate? Looks like wet paint. Why don't you put up a notice? And why don't you have something done about the street lights? Doctor's house, isn't it? Ought to be lit up."

"We are having the house painted," I explained mildly. "There was a notice but I suppose the gale has blown it away. The doctor is out on a call, but if you'll come in . . ." &c., &c. I felt fed up, but I warned myself that the man might be a neurotic under stress, his wife might be in labour, his children might be . . . "It's my little boy," he said, "I'd better wait."

I took him into the surgery, got a wad of cotton wool and some turps and handed it to him. I pulled a chair up and offered some magazines, including that morning's issue of *Punch.* "No thanks," he growled, "they're always months old." I felt myself getting hot where a man wears a collar. A crise de nerfs was pending. To my horror I found myself offering him a blank sheet of paper and saying, "In that case will you be good enough to write out another *Wet Paint* notice? I have a lot to do and the doctor has had nothing to eat since . . ." The phone shrilled. I was able to leave the man with considerable dignity.

I am wondering whether Mr. Bevan is going to get many applications for my job when 1948 comes round. In the meantime I'm reading Yellowlees on "The Human Approach" and taking phenobarb. After a few chapters of this excellent handbook for doctors' wives I realise that my caller should have been m xplicit if he wished to enlist my sympathy. Instead of "It's my little boy" he should have said "It's the little boy in me." I might have liked him then. Maybe.

* * *

I wish that some authority would solve my difficulty. Recently in speaking to a lady who was medically qualified I referred to another qualified lady by the word "doctor" prefixed by the word "lady." To my astonishment I was not allowed to proceed until I had listened to an impassioned protest against the use of such a designation. In mentioning this to another lady in the same qualified category but of a succeeding generation I was amazed to find that she eagerly supported the protest. Each lady objected strongly to being called a woman but did not find fault with the term "woman-doctor." For myself the latter term offends the few æsthetic susceptibilities which I retain and I refuse to include it in my vocabulary. But what word can I use? "Female doctor" is unthinkable, and "feminine doctor" might with truth be applied to some of the male gender. A "doctor of the softer sex" might have been accurate years ago but would be a euphemism now. So far as I can see the only solution is to use a suffix instead of a prefix and speak of a "doctoress." I see that the Oxford Dictionary prefers "doctress" but allows the longer form. In spite of everything I think my original term (which in deference to the ladies I have not used in this note) is quite as correct, more polite, and æsthetically inoffensive.

* * *

When Mrs. Jones, a panel patient 5 months pregnant, had a spontaneous rupture of the membranes the other day she started labour practically forthwith. After some cajoling on the telephone, the district midwife, evidently an exponent of the closed shop ("not really my case under 28 weeks"), went into action. She delivered a five months' fœtus (Albert I) which, unforgivably (as you'll see), made a respiratory movement and cried feebly for a moment or so after the cord was cut. Mr. Jones was informed of the fact and telephoned me, "Will you come at once, doctor, the baby's breathing." On my arrival the fœtus was as defunct as the proverbial doornail, and the midwife was engaged in delivering a twin of the same proportions (Albert II), but this one made no respiratory or vocal effort to enter this wicked world.

All this may seem very humdrum and commonplace, but what about the disposal of the dead? Albert I was obviously not entitled to a stillbirth, birth, death, extra coal, milk and egg, corset, or hot-water bottle certificate, but no undertaker could accept him without some such legal document; at the same time the off-hand disposal of his remains into the fire (indelicate and impractical anyway in these days of fuel shortage), the earth at the bottom of the garden, or my bag (a last resort) might be the subject of idle or malicious neighbourly gossip. Legally Albert I had never been a living being; factually he had, for a brief glorious moment, led an independent existence of which his parents were aware.

The coroner's officer was the only man to provide the answer: "Oh, a miscarriage that squeaked?" (How much better, how much more descriptive than technical jargon!) "Well you don't give any certificate, and do what you like with the remains."

The sum total of this little matter is that I have a couple of fœtuses for sale to offset a considerable telephone account (behind the scene backchat with midwife, fellow practitioner, fuel office, and coroner's office) and a large amount of time which might have been charged to Mrs. Jones's account—only as I said she's a panel patient and apparently all this comes within the scope—all for fifteen bob a year, in other words.

* * *

Our V.A.D. clerk in the Medical Division is obviously suffering from "mal du siécle" (20th-century version). Her latest typewritten report on a barium meal reads: "*Stomach J shaped, atomic. . . .*" Staggered by this discovery, I wondered who was in more urgent need of attention, the trooper whose stomach gracefully sagged, or the V.A.D. who had revealed such explosive forces in her subconscious mind.

"Oh yes, I've met *him*, of course—awfully decent fellow and all that, but frightfully *Third Programme!*"

Letters to the Editor

ETHER ANÆSTHESIA IN 1817?

SIR,—In the *Edinburgh Medical and Surgical Journal* of April, 1847 (vol. 67, p. 564), there is an article entitled "*Facts and Observations on the Inhalation of Sulphuric Ether Vapour as a Narcotic and General Anodyne, with a Description of the Instruments commonly used.*" The article is unsigned and, from the impersonal style of wording, it appears to be of the nature of an editorial commentary on the then recent employment of ether "anæsthesia," although that word is nowhere used by the writer. The greater part is devoted to an account of the work of Jackson and Morton in America, of that of Boote and Liston in London, of a fatal case at Colchester, and of five different patterns of ether inhaler, four of which are illustrated in the accompanying plate, including those used by Squire and Snow.

Apparently the writer does not accept as a new discovery the recent introduction of ether. He writes, "We do not allow that there is, in the administration of this agent to the human system, anything positively new"; and later, "To us it appears to be merely the application in an officinal form of an agent, the anodyne and narcotic effects of which have long been known." The most interesting part of the article, to present-day readers, is the description of a case thirty years previously in which ether had been used for the relief of pain. "In the year 1817," states the writer, "a woman was brought to the Royal Infirmary of this city, by persons who stated that in eating soup, a bone had stuck in the throat and threatened to choke her. She was labouring under great and agonising difficulty of breathing, could not speak, and often pointed to her throat as the seat of all her sufferings." At first the surgeon, whose name is not mentioned, could detect no foreign body, while his assistant "thought that inhalation of the vapour of ether might afford relief." This was used with excellent effect, and next day the surgeon "felt the end of some firm body" and, introducing forceps, he "withdrew a fragment of the superior maxillary bone of a hare." Two days later the patient left the hospital, cured. "The inhalation of the ether, however imperfect, had both relieved the present symptoms of the patient, and had enabled her to undergo more easily than she could otherwise have done the pain of examination for the splinter of bone, and afterwards that accompanying and following extraction."

It is not easy to understand why the writer, in 1847, should feel obliged to go back thirty years in order to find a case to illustrate his remarks, but he proceeds to state that the "narcotic and anodyne effects" of ether inhalation have been "long well known," and he appears to doubt whether "the present mania for etherism previous to operations can do all that is expected from it." He concludes by suggesting that in another twelve months' time the subject may "be considered in its true light and on its actual merits."

It is curious to read this critical contemporary evaluation of what we now regard as a major discovery, and to speculate on what might have happened if that Scottish surgeon of 1817, to whom the writer refers, had pushed his ideas—and his ether—a little further. It would be interesting to know who he was, who thus so nearly discovered the anæsthetic value of ether thirty years before Morton. Or did he actually discover it, while failing to realise its significance?

Edinburgh. DOUGLAS GUTHRIE.

CALCIFEROL FOR TUBERCULOUS ADENITIS

SIR,—In reply to Dr. Bell's inquiry in his letter of Nov. 30, calciferol therapy has been extensively employed at this hospital during the last few months. It was first started in the treatment of lupus vulgaris under the guidance of Dr. G. B. Dowling, and secondly it has been used in a series of cases of tuberculous adenitis. It is as yet too early to give the results in this latter group, but it is hoped to publish a paper on the subject with full pathological investigations in the next few months.

SUZETTE GAUVAIN.

Lord Mayor Treloar Cripples' Hospital.

ERYTHROBLASTOSIS FŒTALIS AND ITS TREATMENT

SIR,—Your editorial (August 17, p. 242) included a comprehensive evaluation of current methods of treating erythroblastosis fœtalis.

The frequent failure of repeated transfusions with Rh-negative blood, and the benefits of the exsanguination-substitution technique are especially important. A number of factors may influence the outcome in these cases. The effect of the stroma of lysed erythrocytes is hypothetical.[1] Toxic manifestations apparently can occur from the administration of red-cell stroma. This was shown by Wiener,[2] who attempted unsuccessfully to use this substance as a desensitising agent in the mother during pregnancy. It is also widely recognised that infants with hæmolytic disease often show listlessness, lack of tone, and inability to take food—symptoms which are frequently associated with toxicity in the newborn.

Consideration should also be given to the effect of the antigen-antibody reaction per se, and the resultant chemical substances which produce an effect similar to anaphylaxis. Inhibition of liver function attendant on improper oxygenation owing to the shock-like state may also be a factor. The effect of overwhelmingly large quantities of bilirubin upon a liver already damaged, with the resultant morphological counterpart of intrahepatic biliary obstruction, has already been stressed.[3] Individually or collectively these influences may well result in liver failure.

The significance of individual reaction to hæmolysis has recently been called to our attention by Rh-positive triplets born to a Rh-negative mother. All three showed varying intensities of hæmolytic disease, although they were all undoubtedly subjected to the same variety and amount of antibody. Similar experiences have been reported by others with regard to twin pregnancies,[4] but with a different interpretation. It was suggested that morphological variations of the placental vessels permitted the return of differing quantities of maternal antibody to each twin. While this theory may apply to the "leakage" of red blood cells, it does not appear likely that anatomical defects are necessary for the return of the antibody molecule through the capillary walls. It appears more probable that the antibody will pass through to each twin in equal concentration and at the same time. Thus the varying degrees of clinical erythroblastosis seen at birth are apt to be affected by differences in susceptibility or individual reaction on the part of the infant.

The concept of a direct action of the antibody upon tissue cells does not appear to be acceptable. This theory would postulate the presence of the antigen in those cells—a condition which is quite rare for the Rh antigen, if it exists at all. Even if present, these antigens should not be expected to behave in an exceptional manner, completely different from that of other isoagglutinogens known to be more frequently present in tissue cells and secretions as the A and B substances. The low incidence of hæmolytic disease due to the isoagglutinins anti-A or anti-B would seem to argue against such a mechanism with regard to the Rhesus antigen.

Whatever mechanism will be eventually proven as the cause of a poor prognosis in many of these infants, it appears likely that the removal of most of the Rh-positive cells and of the circulating antibody shortly after birth prevents the incidence of the more severe pathological and physiological changes. The choice of blood-vessels for the performance of the substitution must depend upon the experience of the operator in the techniques of bleeding. The umbilical vessels should be an excellent route for both the withdrawal and replacement procedures. They can only be used, however, if the decision to perform the substitution is made before birth, and universalised Rh-negative blood is prepared for the replacement.

According to our present knowledge such a course should be followed only when there have been siblings with severe or fatal erythroblastosis. One cannot rely solely upon tests for antibodies in the mother's serum as an accurate indication of impending disease. It is necessary to establish the criteria for therapy by c tions of the newborn infant's clinical and status. The colour of the amniotic fluid and the caseosa, the presence of jaundice, œdema, and megaly, and the response of the baby to stimuli be noted. Blood studies, including the extent of ana the nucleated red-cell count, serum proteins, bl group, and Rh status, should be performed. The hours needed to make these observations do not appre ably affect the safety period so far as the institution treatment is concerned, but do render the use of umbilical vessels impossible.

We have thus far treated 12 infants by the tion technique. The sagittal sinus has been used bleeding in 10 cases and the radial artery in 2. We as yet encountered no complications with the fc route. Of the 12 treated, 9 have recovered. Of babies who died, 2 were treated forty-eight hours longer after birth, and both showed autopsy evidence fully developed kernicterus and liver damage. third was given heparin to facilitate bleeding from radial artery, and at autopsy showed a tentorial lacerati with marked hæmorrhage. Since it has been show that silent intracranial injury is relatively commo it would appear that heparin is a dangerous drug to in the newborn infant.

In conclusion, permit me to say that your clear-c discussion of the problem was most enjoyable, and that should prove of considerable assistance in determinin the paths of further research.

ICTERUS GRAVIS NEONATORUM

SIR,—I was pleased to read Sir Leonard Parsons friendly criticism (Nov. 30) of my article published Nov. 2. The paper invited criticism, and with such big subject I had found it difficult to be concise.

Muir's *Textbook of Pathology* (5th edition) divide jaundice into: (i) hepatogenous, (*a*) obstructive an (*b*) toxic; and (ii) hæmatogenous. The name "tox hepatogenous jaundice" is applied in this textbook conditions arising from damage to the liver parenchym of which acute yellow atrophy and icterus gravis ar cited as outstanding examples. Under the heading hæmatogenous jaundice are included such conditions acholuric jaundice, pernicious anæmia, sickle-cell anæmi and "the type of transient jaundice occurring in newbor children known as icterus neonatorum." Cappell[1] seem to agree that this is essentially a hæmolytic disease, bu further on he writes of the "immature" antibodies an the "mature" (blocking) antibodies as gaining a con centration sufficient to damage the fœtal tissues. "Ce tainly," he concludes, "many infants show severe live damage and the occurrence of cerebral necrosis wi kernicterus is well recognised." There are many othe factors to be considered: the incidence of the diseas with the suggestion that some may inherit the suscepti bility to isoimmunisation; the influence of a hetero specific pregnancy, with the so-called competition of th antigens; the sometimes grave illness of the infant ou of all proportion to the amount of antibody in th maternal serum; and, most significant, the severe illnes of the child with so little evidence of it in the periphera circulation. And so, rightly or wrongly, I took th view that true icterus gravis could not be wholl hæmolytic, but was a toxic condition.

Secondly, Sir Leonard Parsons criticises my opinio that blood-transfusion is satisfactory in erythroblastæmi only. I would inquire as to the average present age o his series of 250 babies, and whether they have bee examined, as mine were, at an average age of 18 month with special attention to possible abnormalities in the central nervous system. I also thought that some babies gravely ill with icterus gravis showed features suggesting the possibility of future kernicterus—deep jaundice, a feeble cephalic cry, extreme hypersensitiveness to light and touch, some suggestion of headraction, and an overall picture of an infant having a ture unlike that of a healthy infant.

---

[1] Cappell, D. F. *Brit. med. J.* Nov. 2, p. 641.

'Finally," Sir Leonard Parsons writes, "Rh antibodies re been found in breast milk, but the evidence that se have any ill effect on the child is, so far, insufficient warrant artificial feeding in preference to breast-ding, although it may be wise to express the breast lk and boil it before giving it to the child." Cappell vises simply heating the expressed milk (how much is t stated), while on the other hand Taylor and Race ommend that the child should be taken off the breast.

I would again stress the importance of homologous od-transfusion; no female in or below child-bearing e should be given whole blood without investigation her Rh group, and all Rh-negative donor panels uld be revised in the light of present knowledge. If is is not done we will in future years reap a rich rvest of anamnestic reactions and perhaps a higher idence of icterus gravis.

Nelson, Lancs. **HENRY THIRD.**

WELFARE OF DEAF CHILDREN

SIR.—As your annotation of Nov. 30 (p. 800) implies, e Education Act offers hope for better training of deaf hool-children, but there is still very little being done for deaf preschool child. It is between the ages of 2 and years that *preferential* consideration is needed because:

1. At this stage the child is keen to learn—is in an ppetitive" phase and more receptive of simple tuition.
2. For the partially deaf child there is enormous value in e early learning of sound language.
3. If the deafness is not recognised by the age of 2 years d training started immediately the child becomes mentally ckward as well as having both hearing and speech defects. his handicap cannot easily be overcome later.

It is not generally recognised that there are so many eaf children in Great Britain. Recent figures by the inistry of Education[1] show that among children under 5 years 1 in every 1000 is deaf and 1 in every 1000 artially deaf: this means that 2 in every 1000 school-ildren need consideration. Since 22% of the present opulation are children up to 15 years of age,[2] it follows at in each community of 120,000 persons there are out 50 deaf or partially deaf children: this is enough call for a separate school with five classes in it. efore school age these 50 children are in need of rgent help.

It is questionable whether it is advisable for very oung children to go to a residential school. The tearing way from home associations at an early life has many isadvantages. If facilities for day schools *and* home uition were made then the child would profit.

It is therefore important to stress:

1. The need for early recognition of deafness by parents and eneral practitioners. Any child not talking or obeying nstructions by the age of 2 years should be suspected of eafness.
2. The need for advisory centres to tell parents and G.P.s hen to send the child for (*a*) recognition of actual deafness, nd treatment if possible; (*b*) grading of the deafness into the ecognised groups of slight, moderate, severe, and total.
3. The need for more teaching centres for (*a*) preschool hildren; (*b*) school-children.
4. The need for more teachers of the deaf. Without these othing can be done to provide for no. 3.

It is hoped that the Medical Research Council sub-ommittee on educational problems of the deaf will soon elease useful and constructive findings both for future xperimental work and for present-day clinical and social mprovements. While awaiting this release other plans an be considered:

Long-term Policy.—(1) Foundation of a centre in London imilar to that in Manchester and several in the U.S.A. with full scope for training teachers, teaching children, and research.

(2) Amalgamation of all the different educational, social, religious, and medical societies dealing with, and interested in, deaf children into one vital force.

Short-term Policy.—(1) Enrolment of teachers for the deaf from demobilised men and women at once.

(2) Arrangement of small "nursery" clinics for preschool children where tuition could be given to the child and the parents. This is explained more fully below.

(3) Arrangement of lectures and meetings for parents.

(4) Provision of speech amplifiers to parents for home use with small children.

(5) Provision of more hearing-aids to individual children (in some even at the age of $4^1/_2$ or 5). It is reasonable to expect that soon the school authorities will allow children in the "moderate" group of partially deaf to go to ordinary schools, with aids which are efficient and strongly made, if preschool tuition has brought the child up to a suitable standard.

(6) Provision of more class amplifiers in schools for the deaf. A "moving up" of some of the moderately deaf would allow more facilities for the remaining more deaf pupils.

(7) Steps to make the hearing public more aware (e.g., by short films, &c.) of the plight of deaf children if neglected, and what can be done for them.

Nursery Clinics.—The preschool child need not, in these days of shortage of teachers for the deaf, be instructed by a fully qualified teacher. A speech therapist with training and experience in teaching lip-reading to infants, or a person with suitable background of the "nanny" type, could, with hearing-aid auxiliaries, take charge of small clinics. The clinics would be attached to ordinary nursery schools or to hospitals and welfare centres. In the clinics the child would be made conscious of the importance of language, as are the children trained by Miss Sylvian Martin at the late Infants Hospital, Vincent Square. Here the preschool child is able to grasp a vocabulary of about 200 words.

Setting up these preschool clinics would cover the time-lag before the educational scheme comes in and increased facilities are made available for this group of children.

So great is the need to "do something" now that hundreds of parents have already banded themselves together to form the Deaf Children's Society, which aims to push forward the urgent claims for better conditions. The society is keen to finance bursaries to the Department of Education of the Deaf, Manchester University, for students intending to become fully qualified teachers, and also to pay for one-year "courses" for the proposed preschool clinic teacher.

Research.—It is a heartening fact that many medical men are becoming more aware of the need for this branch of research; many are conducting research into various pathological and epidemiological aspects, such as deafness caused by intra-uterine infection from the virus of rubella, and the prevention of otitis media in the exanthemata of childhood. Further fields for exploration lie in (1) electronics in audiometry, hearing-aids, and teaching of voice control; (2) electroencephalography in deaf children; (3) all virus diseases as a possible cause of congenital deafness; (4) genetics as applied to deafness; and (5) advance in rational psychology of the deaf child.

ELISABETH EDWARDES
Secretary, Deaf Children's Society.

London, W.C.1.

INVESTIGATION OF MALE INFERTILITY

SIR.—Might one appeal through your columns to pathologists throughout the country to establish a more expert and uniform service for undertaking seminological investigations?

The investigation and treatment of female infertility has advanced greatly within the last few years, but many of the excellent gynæcological advances are made ineffective on account of inadequate investigation and treatment of male infecundity. It is now accepted by authorities that in nearly one-half of the barren marriages some infertility is contributed by the male, and in perhaps one-fifth of all cases the causative factor lies exclusively with the husband. The fact that healthy young males who give no history of a genital lesion frequently produce an azoospermic semen, or one where the proportion of abnormal sperms is excessively high and their viability too short, implies a very serious need not only for adequate diagnosis but for the study of the as yet almost unexplored subject of treatment. If more laboratories would give better service in this work and would agree to make their reports in a more uniform way, it would greatly encourage the clinician in exploring the important matter of therapy.

---

[2] Current Trend of Populations of Great Britain, March, 1942.

For the last eighteen months the Family Planning Association has run a laboratory entirely for the purpose of making seminological analyses and of studying post-coital cervical mucus. The laboratory is now working beyond capacity, and the physician in charge is willing to accept part-time clinical assistants and a certain number of grade I technicians for training. Many laboratories may be glad to send an assistant to acquire this experience and thereby contribute to the possibility of advancing a service of urgent national and individual importance. Correspondence should be addressed to Dr. H. A. Davidson, F.P.A. Laboratory, 33, Wimpole Street, W.1.

ALECK BOURNE
Chairman, Subfertility Committee,
Family Planning Association.

London, S.W.1.

SULPHONAMIDE GRANULOPENIA IN CHILDREN

SIR,—In his letter of Dec. 7 Dr. Suchecki draws attention to the suggestion of Drouet and colleagues that a so-called agranulocytic syndrome possibly embraces both acute leukæmia and true agranulocytosis. He describes the similarity of routine blood-counts in the early stages of both diseases and then states that the true diagnosis may be overlooked in those that are rapidly fatal. He goes on to claim that only "a necropsy or elaborate hæmatological investigations" will reveal the true state of affairs.

It cannot be too often stressed that the information obtained from routine examination of the peripheral blood alone in these cases is misleading. In order to differentiate between true agranulocytosis and acute leukæmia with leucopenia (aleukæmic leukæmia) more definite information must be obtained, and without this information a reliable prognosis cannot be given or rational treatment undertaken.

A careful search for enlarged lymphatic glands, however slight, should be made with a view to biopsy in the obscure case, but the sternal-marrow biopsy should never be omitted since the smear obtained is often of extreme value in diagnosis. The technique of sternal-marrow puncture is very simple and safe, whether performed on adults or children, and this should never be regarded as merely another superfluous clinical investigation of an "elaborate" nature and of academic interest only. Experience is, however, essential if the smears are to be interpreted correctly.

Royal Infirmary, Manchester. FRANK FLETCHER.

VARIATIONS IN THE FEMALE PELVIS

SIR,—Dr. Nicholson and Mr. Sandeman Allen in their article of August 10 state that they have produced evidence to disprove three propositions, of which the first is as follows:

1. "The android pelvis is, as its name implies, a male pelvis; it is caused by some abnormality in sex differentiation, and is associated with male stigmata in the female."

I am puzzled by their statement that "obstetricians who accept the theory hold views on genetics, embryology, and anatomy which would be regarded as unorthodox by the geneticist, the embryologist, and the anatomist." There is considerable evidence that females may have pelves with many features of the type one associates with the male. Elliot Smith and Wood Jones, from their archæological survey of Nubia, mention that in 5 of the bodies found it would have been impossible to fix the sex had not fœtal bones been found in the body cavities. They go on to say that they would otherwise have classified them as males. Furthermore in Prof. Wingate Todd's collection of skeletons of known sex in the Western Reserve University of Cleveland, Caldwell and Moloy found that 32·5% of white women's and 15·7% of black women's pelves were "android." By "android" they mean a pelvis with some or all of the following features:—

Inlet blunt, heart-shaped or wedge-shaped.
Fore-pelvis narrow, and the anterior pubo iliac limbs of the fore-pelvis straight.
Widest transverse close to the sacral promontory.
Posterior iliac portion short.
Sacro-sciatic notch narrow and high arched; thus the segment of the inlet is wide and flat.
Sacrum set forward in the pelvis, decreasing the sagittal measurement.
Pubic rami long and straight edged with a deep true
Bones heavy, angular, and less graceful than in the

They add that the fore-pelvis may be wide, as in android-gynæcoid pelvis, and in this case there may wide subpubic angle to compensate for a male hind-pelvis. They conclude that in the worst the prognosis for vaginal delivery is poor, and indicates cæsarean section; and also that the worst of all are seldom seen outside sterility clinics, and occur in women with amenorrhœa.

The remaining propositions mentioned by Nicholson and Mr. Sandeman Allen were:

2. "The android pelvis and to some extent the anth pelvis are associated with a narrowing of the outlet the pelvis, particularly with contraction of the angle."
3. "The android pelvis is associated with difficulty in labo

"The evidence in rebuttal of these two proposi they say, "is drawn from the radiographical measure ment of 307 women who were eventually delivered the hospital at full term as vertex presentations durin the years 1936–43 inclusive." The series is very smal and one naturally asks how much abnormal materi is likely to be encountered in eight years in a sma country hospital which X rays only about 35 patien yearly from the obstetric point of view. Compare th series of 1000 clinically suspect pelves presented b Méave Kenny (*J. Obstet. Gynæc.* 1944, 51, 277). In the 1000 cases, taken from 10,000 consecutive deliveri she found, using the Caldwell and Moloy classification

Gynæcoid	348	Pithecoid (anthropoid)	[illegible]
Gynæcoid-android ..	110	Platypelloid	[illegible]
Android..	203	Rickety flat	[illegible]
Android-gynæcoid ..	251	Osteomalacic	[illegible]

The 307 cases are stated to include full-term vert presentations only. What happened to abnormal pres tations and to those cases subjected to cæsarean section Also were any patients subjected to surgical inductio of labour? Méave Kenny found that 56% of the suspect cases had android pelves of one type or and reckons that, in normally fertile women, only a 3% of the pelves are likely to be of a pronounced andro type. Thus one might expect to find only about 9 cas in a series of 307 unselected healthy adult English women. If that were so, the exclusion of all abnormalities, such as malpresentations and cases treated by cæsarean section, which at the lowest must total 5% of all cases seen, tends to negative the value of th investigation.

The authors suggest that the posterior sagittal seg ratio, at the brim, is one on which they rely for th identification of the scutiform pelvis. If they identi the android with the scutiform pelvis, their stat appears to be at variance with the findings of Ince a Young in their anthropological survey of 500 pel by X-ray methods (*J. Obstet. Gynæc.* 1940, 47, 130). These authors say that the posterior sagittal segment ratio at the brim is only slightly less in the male than in the female, and that it does not appear to be as important in differentiating android from gynæcoi types as Caldwell and Moloy suggest. At all events one is going to rely on the posterior sagittal inde (percentage ratio of posterior sagittal measurement to that of whole conjugate) why adopt an index of 30 as the upper limit of android or scutiform pelves? This as the authors say, leaves about 10% of their cases in the scutiform class; yet the impression of those seeing large numbers of pelvic X rays is in agreement with Méave Kenny's view—namely, that only 3–5% at most of normal fertile women have android pelves. Had they, for instance, chosen 25 as their sagittal index limit, the "scatter diagram" would show only 4 scutiform pelves instead of 28. I contend, in other words, that by eliminating all abnormalities before they start, and by including as scutiform many pelves which might more properl be called gynæcoid, they "prove" that the scutiform android pelvis is not the fearsome thing that we have n led to believe.

Maeve Kenny found an interference rate of 76·4% android-gynæcoid pelves and one of 82·5% for pure droid pelves, compared with only 12·9% for her 348 næcoid cases. She concluded that the android hindlvis plays a most sinister part in the causation of stocia.

London, W.1. D. G. WILSON CLYNE.

THE ELECTRONIC AND HUMAN BRAIN

SIR,—Many will support, with you, Dr. Walshe's mely plea for more conceptual thinking. It is, as you y, in line with the developments of modern science. ut why limit your exemplifications to the "opposite" hools of Eddington and Bertrand Russell? Why is o mention made of dialectical materialism? Here we ve a philosophy which is, I think, quite satisfying to e scientific mind. It rejects metaphysics, but not nceptual thinking about observed facts. It rejects echanistic materialism, as modern science must reject , but insists that no concepts and entities extraneous om Nature must be introduced in the explanation of tural phenomena. It explains, in general terms, the ws of development and change, and thus helps in the vestigation of particular changes. Finally, whilst reserving a strict respect for facts, it stresses the portance of man in changing the facts, when he acts n them *secundum artem* and not by mere whim or sire.

This is a school of thought sufficiently important, in ritain and abroad, not to be passed over in silence.

London, W.1. E. MONTUSCHI.

CHILD HEALTH

SIR,—Prof. Richard Ellis, in the lecture you reviewed ast week (p. 871), spoke of the work of the late Lord Baden-Powell of Gilwell as the greatest influence for good on the health of the older child.

Gilwell Park is synonymous with camping at its best, and throughout the country other camping grounds, under the auspices of the Boy Scouts' Association, are eaching the elements of hygiene and creating the physique and psychological outlook inalienable to good ealth. The boys have to do everything for themselves, utilising every muscle in their frames, as well as their wits, and the results fully confirm the high opinion of the movement expressed by Professor Ellis. The Boy Scout movement has prepared boys to render signal service to the injured and those in danger of loss of life, and we are not unmindful of those boys with a physical handicap, for whom special tests are devised so that they may join in and enjoy the benefits of scouting.

The more that doctors examine the aims and objects of the movement as concerning the health of the child the more they will understand the need for full ollaboration.

Kew, Surrey. AUSTIN WILLIAMS.

R.N.V.R. OFFICERS' COMMEMORATION FUND

SIR,—During the war no less than 2700 doctors held ommissions in the Royal Naval Volunteer Reserve. They served with great distinction in all classes of ships and in all parts of the world. Many lost their lives. It may therefore interest members of the medical profession to know that the R.N.V.R. Officers' Commemoration Fund has been opened to commemorate in a practical way the part R.N.V.R. officers played in the war, and in particular those who lost their lives. The fund has two objects: (1) to purchase and equip the new premises of the R.N.V.R. Club; and (2) to start an adequate welfare fund to help R.N.V.R. officers and their dependants who may stand in need.

The new club will have a memorial tablet, and relatives of officers who were killed may through this fund have officers' names inscribed on it. This club, started during the war, has grown from nothing to an institution with 0,000 members, and it provides good and cheap meals, accommodation, and amenities, particularly for junior officers. But it must leave its war-time premises, and without help it cannot get into new premises. The administration of the welfare fund is closely integrated with that of King George's Fund for Sailors.

We sincerely hope that many members of the medical profession, so many of whom served in the R.N.V.R., will give their support. The money is urgently needed. R.N.V.R. officers themselves have generously supported the fund, but most of them are young, and it is hoped that the outstanding part that they played in the war (when they formed 80% of the officer strength of the Navy) will commend this appeal favourably to their fellow-countrymen.

Cheques should be sent to Commodore Earl Howe, R.N.V.R. Club, 52, Pall Mall, London, S.W.1.

W. W. ASTOR
Chairman.

London, S.W.1.

Medicine and the Law

Death after Gold Salt

AT an inquest in Manchester recently evidence was given that a 47-year-old woman had died from cerebral hæmorrhage following injections of gold. In 1942 the patient, who had rheumatoid arthritis, had received this therapy in hospital. The condition had improved, but a year later relapsed; she attended hospital for further injections as an outpatient; but since she was unable to make the journey the treatment was continued by her own doctor. In January, 1945, she was again admitted to hospital, where the white-cell count in the blood was found to be below normal: the last two counts before discharge were just within normal limits.

Gold treatment was resumed by the patient's doctor in September, 1945, and the first sign of intolerance appeared after the seventh injection. Even after the eighth injection, which resulted in a bruise on the arm, the patient felt quite well; but subsequent symptoms caused the doctor to discontinue treatment and refer the patient to hospital. A verdict of death by misadventure was recorded by the city coroner, who added that even if a general practitioner himself had no facilities for a blood-count this could be obtained at a hospital

Public Health

Tuberculosis Allowances

THE Ministry of Health has produced a circular (no. 221 46) giving local authorities guidance over the effect of family allowances and the recent increase in the rate of old-age pensions on poor-law relief, tuberculosis allowances, financial assistance under the Blind Persons Act, and contributions towards the cost of hospital treatment and of maternity and child-welfare services.

The purpose of the Family Allowance Act, the Ministry says, is to supplement a man's wages, which otherwise take no account of the size of his family. The allowances payable to the tuberculous under memorandum 266 T already vary according to the size of the family, children's allowances being paid at the rates published in our issue of Dec. 7 (p. 852). If ordinary family allowances were paid in supplement to them, double provision would be made for dependent children, and it is a cardinal principle of the comprehensive insurance plan and health service now being created that double allowances of this kind should be avoided.

A DEPUTATION TO THE MINISTRY

The future of tuberculosis allowances was discussed by a deputation from the Joint Tuberculosis Council and other bodies which waited on the Ministry of Health on Nov. 15. Introduced by Dr. C. K. Cullen, the deputation was received by Sir Arthur Rucker, with Sir Wilson Jameson in the chair. Representatives of the Ministry of National Insurance, the Assistance Board, the Department of Health for Scotland, and other officers of the Ministry of Health were also present.

The Ministry, it was explained, fully accepted the view that tuberculosis calls for special provision; but this would have to be made within the general pattern of the new social legislation. The National Insurance Act would provide benefits in various adversities. For those who needed something more, this would be forthcoming under a National Assistance Bill (now in preparation) which was to sweep away the poor-law and give effect to a new concept of Government assistance. Tuberculosis patients would be basically provided for in this way; but, by virtue of their special needs, the Assistance Board would, it was hoped, be empowered in the new Bill to make payments to needful persons under treatment for pulmonary tuberculosis on a scale higher than the normal scale of assistance applicable to the community as a whole. It was intended that the tuberculosis officer and the dispensary organisation should be associated with the administration of this assistance; and the grant of the special rate of assistance would be conditional on the patient undertaking approved treatment. The discrimination against so-called chronic cases of pulmonary tuberculosis under the present scheme would disappear.

The higher level of assistance would, however, be limited to cases of pulmonary type. In the Ministry's view, persons suffering from non-pulmonary tuberculosis were in a rather different category: it was not necessary to induce them to give up work, while still capable of it, in order to undertake treatment and to lessen the risk of spreading infection. The non-pulmonary patient would be able to receive, besides insurance benefit, supplementary allowances from the Assistance Board, and help from the care committee; and representations to the Assistance Board regarding any individual case would always receive sympathetic consideration.

The deputation sought to urge that the position of the susceptible family of a tuberculous patient was the same whether the case was pulmonary or non-pulmonary. But the Ministry held that, important as this consideration was, it was not of overriding cogency, and to attempt at this stage to extend the special provision to non-pulmonary patients might involve the risk of failing to obtain it for pulmonary patients, for whom a much stronger case could be made out.

It was explained that care and aftercare work for the sick, including the tuberculous, would be the responsibility, under the National Health Service Act, of local health authorities. They would be precluded from giving monetary assistance, but if a voluntary body participated in such work there would be nothing to prevent it using its funds as it wished.

The Ministry took note of criticism regarding the deduction of family allowances from payments under the present tuberculosis scheme, and the alleged inadequacy of the general scale-rates under this scheme.

Infantile Gastro-enteritis

An outbreak of gastro-enteritis in the maternity nurseries, affecting 36 newborn babies, led to the closure of the maternity department of the City General Hospital, Leicester, on Dec. 11. An infant died of gastro-enteritis in the nurseries on Sept. 6, and up to Nov. 17 there were 7 isolated cases, 3 in one nursery and 4 in another, 5 of them proving fatal. Between Nov. 26 and Dec. 1 there were 6 further cases. On Dec. 4 and the succeeding few days there was an explosive outburst, involving 25 further babies, the infection having spread to another emergency nursery. Among the total of 38 cases since Sept. 6 there have been 15 deaths. The diarrhœa or vomiting has developed between the third and sixteenth days, the average day being about the fifth. Some children have had pyrexia and others none. Most of the children who have died have survived until the second week. In treatment, penicillin, sulphaguanidine, and sulphathalidine have been used, but in the severe cases these drugs did not alter the course of the illness. No pathogenic bacteria have been discovered in the stools and the supposition is that the infection is due to an unidentified virus. During the same period some mothers developed mild diarrhœa, and no pathogenic organisms were isolated from their stools.

Similar outbreaks have occurred in St. Joseph's Hospital and Sharoe Green Hospital, Preston, and Cowley Road Hospital, Oxford, at which the maternity wards have been closed.

Infectious Disease in England and W

WEEK ENDED DEC. 7

Notifications.—Smallpox, 0; scarlet fever, whooping-cough, 1783; diphtheria, 313; 6; typhoid, 7; measles (excluding rubella), pneumonia (primary or influenzal), 677; fever, 40; poliomyelitis, 14; polioencephalitis, encephalitis lethargica, 1; dysentery, 76; pyrexia, 128; ophthalmia neonatorum, 60. No of cholera, plague, or typhus was notified during week.

Deaths.—In 126 great towns there were no from scarlet fever or enteric fever, 4 (0) from diphth 3 (0) from measles, 6 (1) from whooping-cough, 6 from diarrhœa and enteritis under two years, and 2 from influenza. The figures in parentheses are thos London itself.

The number of stillbirths notified during the week 264 (corresponding to a rate of 27 per thousand births), including 24 in London.

Parliament

FROM THE PRESS GALLERY

Scotland's Turn

MOVING the second reading of the Scottish Health Service Bill on Dec. 10, Mr. J. WESTWOOD p out that it differed from the English Bill in some as was but fitting, for Scotland had her own legal traditions, and system of local government. M the geographical distribution of her population different.

THE HEALTH CENTRES

In the general-practitioner service, the only concerned health centres. Local conditions varied and, as the country was not an unmanageable unit had thought it best that the early steps in health development should be undertaken directly by Secretary of State. In that way the lessons of the e years could best be learned and generally applied. Scottish local authorities had made no serious objec to this course, and the medical profession had prefe that it should be so. The Bill allowed these to be gated to local authorities, but Mr. Westwood said he not intend to exercise that power in the early experimental years of the service.

In Scotland, as in England, although payment capitation fees would represent the larger part of doctor's remuneration, there would also be an elemen basic salary. That doctors in Scotland should look u this fearfully surprised Mr. Westwood, for basic sala by another name had for the last thirty years been essential feature of the Highlands and Islands Med Service, to which so many tributes had been paid doctors themselves. As in England, sale and purch of medical practices coming within the new ser would be prohibited, and Scottish doctors would sh in the £66 million provided by the Government compensation.

The Committee on Scottish Health Services, wh reported in 1936, had expressed the view that hospi administration should be one service and should organised on regional lines. But while everyone accept the need for a regional hospital system, it was not equa appreciated that it was not possible so long as there w two different forms of hospital administration and own ship. In Scotland there were 250 hospitals belongi to 55 local authorities, and about another 220 volunta hospitals, practically every one of which had a separ governing body. With such a multiplicity of authorit there would be overlapping, unnecessary competiti and, worst of all, gaps in the hospital service. As far he could judge from his discussions, these propos were generally acceptable to those in Scotland who h to work in hospitals, and even to some of the loc authority and voluntary-hospital people, whose respo sibilities were being taken away. The maximum indepe dence would be left with the boards of manageme and he intended so far as he could to leave the f regional boards to get on with their job.

OTHER DIFFERENCES

Three features of the hospital proposals, he continued, re peculiar to Scotland. The English Act put the ponsibility for the ambulance service on the local alth authorities, but the Scottish Bill put it on the cretary of State. This was the right thing to do in otland where the local health authorities were smaller area and population.

The next difference concerned the teaching hospitals. om an early stage of the Government's discussions he d been clear that the English arrangement was unsuitable for Scotland. Although the number of hospital ds in Scotland was only about a tenth of the total for e United Kingdom, Scotland was training about a ird of the medical students—a remarkable achievement. Therefore, if the teaching hospitals were taken t of the regional ambit, the core of the Scottish hospital rvice would have gone. He had therefore tried to ame an alternative scheme with the same general aim f safeguarding the position of medical education. He ought that the universities would accept generally at the Bill would enable them to discharge their sponsibilities to their own satisfaction. The Bill laid clear duty on the responsible Minister, and through m on the regional boards and boards of management, o make available all the necessary facilities for clinical aching and research. When the regional board drew p its scheme for the constitution of boards of managements for hospitals it must consult the university to stablish in which hospitals teaching was to be carried on, and on the boards of these hospitals the university must be represented. There would be a medical education committee in each region to advise the board on all matters relating to the hospital services which affected medical education.

The Bill also provided that boards of management, whether of teaching or non-teaching hospitals, would in the first place retain the endowments of their hospital. In the new conditions, when many endowments would not be needed for their original purpose, some review and reallocation was necessary.

Turning to the local health authorities, Mr. Westwood said that their most important function in the future was e social side of health care. This was linked with their broad duties in connexion with the control of infectious diseases. But they had yet another part to play in the new service. They represented the consumers, and for this reason they nominated a third of the members of the executive councils responsible for the general-practitioner services. They would also be consulted in the appointment of regional boards and boards of management. In framing the regulations under the Bill it would be the earnest desire of the Government to have full and free discussions with all the interests concerned, including the organisations of professional men and women on whose good will and coöperation the success of the health service depended.

THE DEBATE

On behalf of the Opposition Mr. J. S. C. Reid moved an amendment calling for the rejection of the Bill. It put, he declared, too much power in the hands of the Minister and left too little scope for initiative and sponsibility on the part of those who were to run the service. Almost all the objectionable provisions which injured the patient by undermining the independence of the medical profession centred on the control of the distribution of doctors, yet the average number of people per general practitioner in Scotalnd was 2000, and only 3 areas could be held to be underdoctored. He was amazed that the teaching hospitals had been treated so much less favourably than in the English Bill and for such flimsy reasons. In England the teaching hospitals through their board of governors were in direct contact with the Minister and with the universities, and kept their endowments. In Scotland in future they would only have boards of management and become mere units in a large scheme, while all their endowments were subject to reallocation.

Sir John Graham Kerr dubbed the Bill the product of diligent artificers working in the murky recesses of a Whitehall office. At present the finest material was coming into the science of medicine. It was the leaders of the profession who were training it. But they did that work because they realised that it would give them an opportunity to inspire their students, and that they would be paid back, indirectly, by forming a great clientele of practitioners who would come back to consult them later on. The type of man who went into a university, or other school of medicine, and later into the profession, was not the sort of person who was interested in a salaried service in which promotion went merely by seniority. If the Bill were passed into law it would be one of the greatest disasters to the health of the people.

Colonel Walter Elliot held that the Bill would be a better one if it followed Scottish traditions instead of trailing at the heels of the English Bill, or indeed of its Welsh instigator. Why had the Hetherington report been thrown overboard and this new parentless institution brought in? In carrying out the Highlands and Islands Service it had not been found necessary to nationalise a single hospital.

In summing up, Mr. G. Buchanan, joint Under-Secretary of State, said they had sought to avoid the difficulty of defining a teaching hospital; and to leave out of this new experiment 230 hospitals—almost half the total—would make a sham of the whole scheme. They had been criticised for not giving enough power to local government. But nowadays it was said that there must be some form of workers' control. And here the workers were the doctors. They must be given some rights and on the whole they did not want the local-authority set-up.

Petition against Vivisection

In the House of Commons on Dec. 12 Mr. Peter Freeman presented a humble petition protesting against the practice of vivisection on live animals with or without anæsthetics. The petition, signed by 1972 petitioners, declared vivisection to be morally unjustifiable, scientifically useless, dangerous, and demoralising to the community, and earnestly prayed that the House would pass a Bill withdrawing the sanction of the law from its practice.

QUESTION TIME

Psychiatrists on Selection Boards

Mr. Geoffrey Cooper asked the Secretary of State for War on what grounds a decision had been made to remove qualified psychologists and psychiatrists from officer selection boards, in view of the fact that these experts devised the successful techniques now in use.—Mr. F. J. Bellenger replied: The function of the Service psychiatrist is to advise the executive authorities on matters of mental health and adjustment. It is open to the presidents of officer selection boards to consult the Service psychiatrists, or specialists in other branches of the medical profession, if they find reason to do so. Psychiatrists and psychologists are both consulted in the formulation of the technique adopted by the boards.

Mr. Cooper: Have psychologists and psychiatrists been dropped? The answer does not make that point clear.—Mr. Bellenger: They have not been dropped, but they are not now necessarily members of these selection boards. —Mr. Cooper: Does the Minister know that the presence of psychologists and psychiatrists on these boards during the war won the confidence of the serving men, and increased the number of other ranks who applied for commissions? —Mr. Bellenger: As long as the services of psychiatrists are made available, if necessary, that is all, I think, my hon. friend can ask for. I may tell him that there was a good deal of objection to these psychiatrists among the men.

Brigadier A. H. Head: Is the Minister aware that all other ranks did not share the view of the hon. member, and that some of them referred to the psychiatrists as "trick cyclists"?—Mr. Cooper: Was that on the part of senior officers or other ranks?—Mr. Bellenger: I am well aware of that, but I think we ought to get this question in its correct perspective. Psychiatrists were of great value in many cases.

Release of R.A.M.C. Officers Serving in India

Major E. A. H. Legge-Bourke asked the Secretary of State for War if he would state, by age and service groups, the number of R.A.M.C. officers now serving in the India Command whose release had been compulsorily deferred distinguishing specialist and general duties officers.—Mr. Bellenger replied: Up to Nov. 15 there has been no case

The Ministry, it was explained, fully accepted the view that tuberculosis calls for special provision; but this would have to be made within the general pattern of the new social legislation. The National Insurance Act would provide benefits in various adversities. For those who needed something more, this would be forthcoming under a National Assistance Bill (now in preparation) which was to sweep away the poor-law and give effect to a new concept of Government assistance. Tuberculosis patients would be basically provided for in this way; but, by virtue of their special needs, the Assistance Board would, it was hoped, be empowered in the new Bill to make payments to needful persons under treatment for pulmonary tuberculosis on a scale higher than the normal scale of assistance applicable to the community as a whole. It was intended that the tuberculosis officer and the dispensary organisation should be associated with the administration of this assistance; and the grant of the special rate of assistance would be conditional on the patient undertaking approved treatment. The discrimination against so-called chronic cases of pulmonary tuberculosis under the present scheme would disappear.

The higher level of assistance would, however, be limited to cases of pulmonary type. In the Ministry's view, persons suffering from non-pulmonary tuberculosis were in a rather different category: it was not necessary to induce them to give up work, while still capable of it, in order to undertake treatment and to lessen the risk of spreading infection. The non-pulmonary patient would be able to receive, besides insurance benefit, supplementary allowances from the Assistance Board, and help from the care committee; and representations to the Assistance Board regarding any individual case would always receive sympathetic consideration.

The deputation sought to urge that the position of the susceptible family of a tuberculous patient was the same whether the case was pulmonary or non-pulmonary. But the Ministry held that, important as this consideration was, it was not of overriding cogency, and to attempt at this stage to extend the special provision to non-pulmonary patients might involve the risk of failing to obtain it for pulmonary patients, for whom a much stronger case could be made out.

It was explained that care and aftercare work for the sick, including the tuberculous, would be the responsibility, under the National Health Service Act, of local health authorities. They would be precluded from giving monetary assistance, but if a voluntary body participated in such work there would be nothing to prevent it using its funds as it wished.

The Ministry took note of criticism regarding the deduction of family allowances from payments under the present tuberculosis scheme, and the alleged inadequacy of the general scale-rates under this scheme.

Infantile Gastro-enteritis

An outbreak of gastro-enteritis in the maternity nurseries, affecting 36 newborn babies, led to the closure of the maternity department of the City General Hospital, Leicester, on Dec. 11. An infant died of gastro-enteritis in the nurseries on Sept. 6, and up to Nov. 17 there were 7 isolated cases, 3 in one nursery and 4 in another, 5 of them proving fatal. Between Nov. 26 and Dec. 1 there were 6 further cases. On Dec. 4 and the succeeding few days there was an explosive outburst, involving 25 further babies, the infection having spread to another emergency nursery. Among the total of 38 cases since Sept. 6 there have been 15 deaths. The diarrhœa or vomiting has developed between the third and sixteenth days, the average day being about the fifth. Some children have had pyrexia and others none. Most of the children who have died have survived until the second week. In treatment, penicillin, sulphaguanidine, and sulphathalidine have been used, but in the severe cases these drugs did not alter the course of the illness. No pathogenic bacteria have been discovered in the stools and the supposition is that the infection is due to an unidentified virus. During the same period some mothers developed mild diarrhœa, and no pathogenic organisms were isolated from their stools.

Similar outbreaks have occurred in St. Joseph's Hospital and Sharoe Green Hospital, Preston, and Cowley Road Hospital, Oxford, at which the maternity wards have been closed.

FROM THE PRESS GALLERY

Scotland's Turn

MOVING the second reading of the Scottish Na Health Service Bill on Dec. 10, Mr. J. WESTWOOD poi out that it differed from the English Bill in some as was but fitting, for Scotland had her own legal sy traditions, and system of local government. M the *geographical distribution of her population* different.

THE HEALTH CENTRES

In the general-practitioner service, the only concerned health centres. Local conditions varied and, as the country was not an unmanageable unit, had *thought it best that the early steps in health* development should be undertaken directly by Secretary of State. In that way the lessons of the years could best be learned and generally applied. Scottish local authorities had made no serious to this course, and the medical profession had preferred that it should be so. The Bill allowed these to be dele gated to local authorities, but Mr. Westwood said he did not intend to exercise that power in the early and experimental years of the service.

In Scotland, as in England, although payment by capitation fees would represent the larger part of the doctor's remuneration, there would also be an element of basic salary. That doctors in Scotland should look upon this fearfully surprised Mr. Westwood, for basic salaries by another name had for the last thirty years been an essential feature of the Highlands and Islands Medical Service, to which so many tributes had been paid by doctors themselves. As in England, sale and purchase of medical practices coming within the new service would be prohibited, and Scottish doctors would share in the £66 million provided by the Government as compensation.

The Committee on Scottish Health Services, which reported in 1936, had expressed the view that hospital administration should be one service and should be organised on regional lines. But while everyone accepted the need for a regional hospital system, it was not equally appreciated that it was not possible so long as there were two different forms of hospital administration and ownership. In Scotland there were 250 hospitals belonging to 55 local authorities, and about another 220 voluntary hospitals, practically every one of which had a separate governing body. With such a multiplicity of authorities there would be overlapping, unnecessary competition and, worst of all, gaps in the hospital service. As far as he could judge from his discussions, these proposals were generally acceptable to those in Scotland who had to work in hospitals, and even to some of the local-authority and voluntary-hospital people, whose responsibilities were being taken away. The maximum independence would be left with the boards of management and he intended so far as he could to leave the five regional boards to get on with their job.

OTHER DIFFERENCES

hree features of the hospital proposals, he continued, e peculiar to Scotland. The English Act put the ponsibility for the ambulance service on the local lth authorities, but the Scottish Bill put it on the retary of State. This was the right thing to do in tland where the local health authorities were smaller area and population.

he next difference concerned the teaching hospitals. m an early stage of the Government's discussions he l been clear that the English arrangement was unsuit- le for Scotland. Although the number of hospital ds in Scotland was only about a tenth of the total for e United Kingdom, Scotland was training about a rd of the medical students—a remarkable achieve- nt. Therefore, if the teaching hospitals were taken t of the regional ambit, the core of the Scottish hospital vice would have gone. He had therefore tried to me an alternative scheme with the same general aim safeguarding the position of medical education. He ought that the universities would accept generally t the Bill would enable them to discharge their ponsibilities to their own satisfaction. The Bill laid lear duty on the responsible Minister, and through n on the regional boards and boards of management, make available all the necessary facilities for clinical ching and research. When the regional board drew its scheme for the constitution of boards of manage- ents for hospitals it must consult the university to tablish in which hospitals teaching was to be carried , and on the boards of these hospitals the university ust be represented. There would be a medical educa- on committee in each region to advise the board on all atters relating to the hospital services which affected edical education.

The Bill also provided that boards of management, hether of teaching or non-teaching hospitals, would in e first place retain the endowments of their hospital. the new conditions, when many endowments would ot be needed for their original purpose, some review d reallocation was necessary.

Turning to the local health authorities, Mr. Westwood id that their most important function in the future was social side of health care. This was linked with eir broad duties in connexion with the control of fectious diseases. But they had yet another part to lay in the new service. They represented the con- mers, and for this reason they nominated a third of the embers of the executive councils responsible for the eneral-practitioner services. They would also be con- ulted in the appointment of regional boards and boards f management. In framing the regulations under the Bill it would be the earnest desire of the Government to ave full and free discussions with all the interests con- erned, including the organisations of professional men nd women on whose good will and coöperation the uccess of the health service depended.

THE DEBATE

On behalf of the Opposition Mr. J. S. C. **REID** moved n amendment calling for the rejection of the Bill. t put, he declared, too much power in the hands of the inister and left too little scope for initiative and esponsibility on the part of those who were to run the ervice. Almost all the objectionable provisions which njured the patient by undermining the independence of he medical profession centred on the control of the istribution of doctors, yet the average number of people er general practitioner in Scotalnd was 2000, and only 3 areas could be held to be underdoctored. He was mazed that the teaching hospitals had been treated so much less favourably than in the English Bill and for such flimsy reasons. In England the teaching hospitals through their board of governors were in direct contact with the Minister and with the universities, and kept their endowments. In Scotland in future they would only have boards of management and become mere units in a large scheme, while all their endowments were subject o reallocation.

Sir **JOHN GRAHAM KERR** dubbed the Bill the product of diligent artificers working in the murky recesses of a Whitehall office. At present the finest material was coming into the science of medicine. It was the leaders of the profession who were training it. But they did that work because they realised that it would give them an opportunity to inspire their students, and that they would be paid back, indirectly, by forming a great clientele of practitioners who would come back to consult them later on. The type of man who went into a university, or other school of medicine, and later into the profession, was not the sort of person who was interested in a salaried service in which promotion went merely by seniority. If the Bill were passed into law it would be one of the greatest disasters to the health of the people.

Colonel **WALTER ELLIOT** held that the Bill would be a better one if it followed Scottish traditions instead of trailing at the heels of the English Bill, or indeed of its Welsh instigator. Why had the Hetherington report been thrown overboard and this new parentless institution brought in? In carrying out the Highlands and Islands Service it had not been found necessary to nationalise a single hospital.

In summing up, Mr. G. **BUCHANAN**, joint Under-Secretary of State, said they had sought to avoid the difficulty of defining a teaching hospital; and to leave out of this new experiment 230 hospitals—almost half the total—would make a sham of the whole scheme. They had been criticised for not giving enough power to local government. But nowadays it was said that there must be some form of workers' control. And here the workers were the doctors. They must be given some rights and on the whole they did not want the local-authority set-up.

Petition against Vivisection

In the House of Commons on Dec. 12 Mr. **PETER FREEMAN** presented a humble petition protesting against the practice of vivisection on live animals with or without anæsthetics. The petition, signed by 1972 petitioners, declared vivisection to be morally unjustifiable, scientifically useless, dangerous, and demoralising to the community, and earnestly prayed that the House would pass a Bill withdrawing the sanction of the law from its practice.

QUESTION TIME

Psychiatrists on Selection Boards

Mr. **GEOFFREY COOPER** asked the Secretary of State for War on what grounds a decision had been made to remove qualified psychologists and psychiatrists from officer selection boards, in view of the fact that these experts devised the successful techniques now in use.—Mr. F. J. **BELLENGER** replied: The function of the Service psychiatrist is to advise the executive authorities on matters of mental health and adjustment. It is open to the presidents of officer selection boards to consult the Service psychiatrists, or specialists in other branches of the medical profession, if they find reason to do so. Psychiatrists and psychologists are both consulted in the formulation of the technique adopted by the boards.

Mr. **COOPER**: Have psychologists and psychiatrists been dropped? The answer does not make that point clear.—Mr. **BELLENGER**: They have not been dropped, but they are not now necessarily members of these selection boards. —Mr **COOPER** Does the Minister know that the presence of psychologists and psychiatrists on these boards during the war won the confidence of the serving men, and increased the number of other ranks who applied for commissions? —Mr. **BELLENGER**: As long as the services of psychiatrists are made available, if necessary, that is all, I think, my hon. friend can ask for. I may tell him that there was a good deal of objection to these psychiatrists among the men.

Brigadier A. H. **HEAD**: Is the Minister aware that all other ranks did not share the view of the hon. member, and that some of them referred to the psychiatrists as "trick cyclists"?—Mr. **COOPER**: Was that on the part of senior officers or other ranks?—Mr. **BELLENGER**: I am well aware of that, but I think we ought to get this question in its correct perspective. Psychiatrists were of great value in many cases.

Release of R.A.M.C. Officers Serving in India

Major E. A. H. **LEGGE-BOURKE** asked the Secretary of State for War if he would state, by age and service groups, the number of R.A.M.C. officers now serving in the India Command whose release had been compulsorily deferred distinguishing specialist and general duties officers.—Mr. **BELLENGER** replied: Up to Nov. 15 there has been no case of compulsory deferment of either a specialist or a general-duty R.A.M.C. officer during the last three months.

Supersonic Sound and Health of Workers

Mr. C. W. DUMPLETON asked the Lord President of the Council whether research was proceeding into the possible effects of supersonic sound upon the health of workers in the manufacture of turbo-jet aero-engines.—Mr. HERBERT MORRISON replied : The Medical Research Council are making preliminary inquiries on the subject, and when these are completed consideration will be given to the question of a programme of research.

Board of Control

Mr. R. SARGOOD asked the Minister of Health what was the annual cost to the National Exchequer of the Board of Control of Mental Hospitals and Institutions.—Mr. A. BEVAN replied : *The net cost of the board for 1945–46 was £237,000, of which £58,000 was in respect of the board's office, the remainder being the cost of grants for ex-Service mental patients and the cost of the State institutions for mental defectives of dangerous propensities.*

Social Surveys

In the course of a reply, Mr. GLENVIL HALL stated that the staff of Social Survey were engaged on an illness survey *(for the Ministry of Health), a survey of the incidence of deafness in the country (for the Medical Research Council),* and one on the employment of miners with pneumoconiosis (for the M.R.C. and the Ministry of Fuel and Power).

Preparation of Sera

Mr. PETER FREEMAN asked the Home Secretary whether a licence was required where experiments on living animals were claimed to be used for veterinary purposes ; whether he was aware of the unsatisfactory condition of many horses and other animals used for the preparation of sera for such conditions ; whether such institutions were visited by his officers or the police ; and whether he had any record of the number of such institutions.—Mr. CHUTER EDE replied : I am advised that a licence under the Act of 1876 is required for experiments made to discover or test sera to be used for veterinary purposes, but not for procedures undertaken *merely for the production of such sera. Places used solely* for this purpose are neither visited by my inspectors nor registered by my department. The police do not visit them as a matter of routine.

Mass Radiography

Replying to a question, Mr BEVAN stated that nineteen mass radiography units were operating in England and Wales. Up to June 30 approximately 1,111,000 persons were examined, of whom 4200 were diagnosed as suffering from active tuberculous conditions.

Obituary

ANTHONY RICHARD NELIGAN

M.D. LOND., D.T.M. & H.

Dr. A. R. Neligan, who died on Dec. 8 in Birmingham at the age of 68, had been carrying on his consulting work in Droitwich till two days before his death.

Born in Tralee, co. Kerry, the son of Dr. J. W. Neligan, he studied medicine at Barts, where he carried off the Brackenbury scholarship, the Matthews Duncan gold medal, and the Skynner and Burrows prizes. In 1903 he graduated M.B., and he took his M.D. three years later. After holding house-appointments at Barts, he was appointed in 1906 physician to the British legation at Teheran, and the next twenty years he spent in Persia. As British representative on the Persian Sanitary Council he did much to improve the public health of the country. And in a balanced and comprehensive survey of the Persian health services, published in our columns in 1926, he was able to describe the introduction of a public vaccination service, the establishment of a Pasteur institute, and some progress in sanitation.

After leaving Teheran in 1926 he spent over a year visiting rheumatic hospitals, clinics, and spas in Europe and America, and on his return to England he was appointed superintendent of the Red Cross Clinic for Rheumatism, in London. In 1931 he finally settled in Droitwich, where he was appointed physician to the Royal Brine Baths Clinic. A member of the International Society of Medical Hydrology, the International against Rheumatism, and the Royal Society of Dr. Neligan made valuable contributions to cussions on fibrositis and arthritis. He had training for his own specialty, but over and he had a wide background of knowledge, and he all his life a student, reading widely and keeping abreast of advances not only in his own de also in general medicine.

Dr. Neligan leaves a widow, a daughter, and who is also a doctor.

ROBERT LEE MOORE

L.R.C.P.E.

Dr. R. L. Moore died on Nov. 30, at Bangor, co. where he had carried on an extensive practice fo fifty years. Born in Belfast, he was educated the Royal Academical Institution and at the L Institute. In 1890 he took the Scottish Conjoint tion. Closely associated with the Bangor Hospital its beginning as a small cottage hospital, he was governor of the present institution. He was justice of the peace. His fund of stories about old personalities and events was inexhaustible, and h an authority on co. Down folk-lore and dialect. A me of the Royal Ulster Yacht Club and the Bangor club, Dr. Moore was a noted athlete and ass football player in his youth. His wife survives him three daughters and two sons, one of whom, Dr. B. Moore, is clinical pathologist to the Mater [illegible] A third son died in Java while a prisoner-of-war.

Births, Marriages, and Deaths

BIRTHS

BETTS.—On Oct. 28, the wife of Dr. J. W. Betts—a daughter.

BLANSHARD.—On Dec. 11, in London, the wife of Dr. Paul —a daughter.

CLARKE.—On Dec. 11, the wife of Dr. J. G. R. Clarke—a da

COOPER.—On Nov. 18, at Newcastle, the wife of Captain J. R. R.A.M.C., of Darlington—a daughter.

CUTHBERT.—On Dec. 10, in London, the wife of Dr. J. B. C —a son.

DAVIES.—On Dec. 8, in London, the wife of Dr. J. V. S. A. —a son.

DEMPSEY.—On Dec. 10, in London, the wife of Major Dempsey, R.A.M.C.—a son.

DENNISON.—On Dec. 8, at East Grinstead, the wife of Dr. Dennison—a daughter.

DRURY-WHITE.—On Sept. 20, at Maymo, Burma, Dr. Jean White, wife of Mr. Roger de Coverley—a daughter.

GORDON-WILSON.—On Dec. 6, at Guildford, the wife of Dr. Cl Gordon-Wilson—twin daughters.

HALLETT.—On Dec. 11, at Guildford, the wife of Mr. G. S Hallett, F.R.C.S.—a son.

HOLLINS.—On Dec. 9, at Dorchester, the wife of Dr. C. H —a daughter.

HOPKINS.—On Dec. 3, at Ismailia, Egypt, the wife of Philip Hopkins, R.A.M.C.—a daughter.

HOUGHTON.—On Dec. 7, at Leamington Spa, the wife of Dr. Houghton—a son.

IRVINE.—On Dec. 10, at Hove, the wife of Dr. L. C. D. —a daughter.

JACOBS.—On Dec. 9, in London, the wife of Dr. J. J. M. —a son.

MORRISON.—On Dec. 7, at Singapore, the wife of Dr. Hugh —a son.

OWEN.—On Dec. 8, in London, the wife of Dr. M. W. L. —a daughter.

PATON.—On Dec. 8, at Leicester, the wife of Dr. H. O. P —a son.

RIVETT.—On Dec. 8, at Leeds, the wife of Dr. P. A. H. R —a daughter.

ROLFE.—On Dec. 9, at Hampstead, the wife of Dr. D. A. R —a daughter.

SHAW.—On Dec. 8, in London, the wife of Surgeon-Lieutenant J Shaw, R.N.V.R.—a son.

MARRIAGES

HAMLYN—PRATT.—On Dec. 7, at Aldershot, Edward Ham M.B., captain R.A.M.C., to Enid Pratt

HERDMAN—PEARCE.—On Dec. 10, at Harrow-on-the-Hill, J Phipps Herdman, B.M., to Sheila Kathleen Pearce.

REDDINGTON—GOODALL.—On Dec. 7, in London, North Reddington, F.R.C.S., to Kathleen Mary Goodall.

RUFFMAN—CUMBERLEGE.—On Dec. 5, at Newcastle-on-T Alan Ruffman, M.B., to Yvonne Rhoda Cumberlege.

DEATHS

COLLINS.—On Dec. 12, in London, Sir William Job Collins, K.C. M.D., M.S., B.SC. Lond., F.R.C.S., aged 87.

HERON.—On Dec. 7, David Heron, F.R.C.S.I.

MCTURK.—On Dec. 8, at Newton Stewart, James McTurk, L.R.C.

MILNER.—On Dec. 8, at Torquay, Vincent Milner, M.B. Edin

NELIGAN.—On Dec. 8, at Birmingham, Anthony Richard Nelig M.D. Lond., D.T.M.& H., of Droitwich.

WHITTINGDALE.—On Dec. 11, John Flasby Lawrance Whittingd O.B.E., M.B. Camb.

Notes and News

APPEAL TO WOMEN SPECIALISTS

HE Central Medical War Committee is experiencing ulty in securing enough men to meet the requirements e Services and accelerate the release of specialist officers, e demobilisation is lagging far behind that of medical ers generally. At the suggestion of the Minister of Health committee is now appealing for women volunteers, not e the age of 40, qualified in the specialties of gynæcology, thetics, pathology, or radiology, to serve in the Army .A.F. There is at present a special need for gynæcologists ork among the families of Servicemen overseas, particu- y in the B.A.O.R. The period of service for recruits g the Forces in 1947 will be two years, but volunteer ialists above the age of 30 may, if they wish, serve for onths only. Offers should be addressed to the secretary e committee at B.M.A. House, Tavistock Square, W.C.1, in Scotland, to the secretary of the Scottish Central Medical r Committee at 7, Drumsheugh Gardens, Edinburgh.

GAZELLE BOY

VER since Peter the Wild Boy was found walking on all s, climbing trees, and feeding on grass and moss near celin in 1725 and brought to England to be a protégé of rge I and to be exhibited to the nobility as an example one nurtured by a wild beast (in his case a she-bear was the ost popular postulated foster-mother), tales have cropped up intervals about wolf boys, mainly from India, particularly cknow, where a gullible British resident at the Indian urt had many such boys produced for his inspection. Most them were idiots, but at least one had been brought up as impostor.[1] In 1903 a "baboon boy" was captured in uth Africa[2]; but he was described as "remarkably telligent," and so there may be some truth in the suggestion at he had been fostered by a baboon, which, after all, is a imate. But the latest story of the "gazelle boy" from aq, who, from constant practice in running with the herd, as credited with a speed of 40 m.p.h., turns out to be a mplete hoax. When his photograph was published in the ily press some thought they could detect a lighter shade the boy's arm, suggesting that he had worn a shirt. t it appears that the tale was based on the escape and apture of a mentally deficient boy from an asylum in ria.

TWO NEW BRITISH JOURNALS

THE Nutrition Society is to sponsor a new quarterly, the British Journal of Nutrition, and it is hoped that the first number will appear within the next six months. Papers may now be submitted to the chairman of the editorial board, Dr. S. K. Kon, National Institute for Research in Dairying, hinfield, near Reading, Berks. The need for a journal of his kind has been apparent for a long time, and there will be o lack of excellent material.

The newly founded Society for General Microbiology, f which Sir Alexander Fleming, F.R.S., is president, will ue the first number of its new *Journal of General Microbiology* in January. The society was founded for the study of acteria, micro-fungi, microscopic algæ, protozoa, and viruses, cluding their structure, development, physiology, nutrition, enetics, cytology, ecology, antibiotic activity, and reaction chemotherapeutic agents. The journal will consist of three mbers in the year and it is hoped to increase that number er. The annual subscription is 50*s*. Papers for publication hould be sent to Dr. A. A. Miles, National Institute for Medical Research, Hampstead, London, N.W.3.

Both journals will be published by the Cambridge University Press, Bentley House, 200, Euston Road, London, N.W.1, o whom all non-editorial correspondence should be addressed.

DISINFESTATION OF AIRCRAFT

THE growth of air travel has added greatly to the difficulties of quarantine precautions. It is important, for example, to prevent mosquitoes infected with the yellow-fever virus from reaching areas, such as India, to which the disease has not yet spread despite the existence there of suitable vectors. Aircraft are now disinfested as a routine almost everywhere he tropics. The method consists in releasing a mist of concentrated insecticide, which permeates the air-space inside the aeroplane without harm to the passengers. Garnham, in East Africa,[1] has shown that, given an exposure of at least fifteen minutes, a number of pyrethrum or D.D.T. preparations are effective; a simple paraffin extract of Kenya pyrethrum (1 lb. to the gallon) is efficient, but, like all pyrethrum preparations, it must be used fresh.

One snag is that mosquitoes may retire into out-of-the-way places, such as the hollow interiors of the wings or behind panelling; but these places can be disinfested by increasing the dose or by directing the sprayer into the blind spaces. Perhaps a more serious risk, to which Garnham draws attention, lies in the incapacity of these mists to penetrate fabrics, so that mosquitoes settling inside coat-sleeves are protected. Moreover, removal and shaking of the coat is not enough, for tests have shown that mosquitoes hidden there resist quite rough handling.

SPANISH INTO ENGLISH

IN a pocket dictionary,[1] appropriately dedicated to Dr. Josep Trueta, Mr. Maurice McElligott, F.R.C.S.I., has provided a convenient tool for doctors who wish to read articles in the original Spanish. Yet it is to be doubted whether those who make this attempt are unduly confounded by the medical terms, many of which are nearly identical with their English equivalents: "ectropión," "metabolismo," and "septicemia" are examples taken at random, though there are several on every page of the book. In a second edition he might omit some of these samples of the lingua franca of medicine in favour of terms and expressions likely to puzzle, even though they have no medical bearing in other contexts. In arrangement and typography the book is thoroughly attractive, and the author's assurance of its accuracy appears in the preface.

BATTLE SCHOOL FOR FIRST-AIDERS

PLAINLY it is impossible to teach first-aid workers the theory behind all they learn. This being so, instruction tends to take the form of rigid dogma, teachers and pupils counting themselves content if the catechism is accurately remembered; and the same is true of the usual formal exercises. Top marks in a test under these conditions is no guarantee of even a passable showing in the rough and tumble of reality. This consideration prompted the founding of the Casualties Union, which is dedicated to realism in training. The union teaches the first-aider to use his intelligence as well as his memory; the training he is offered is based on war-time experience that he can no more identify and treat injuries by the 1, 2, 3 in the little book than can the doctor recognise and relieve the condition of his patients by recall of the classical description in the textbook. The union has been at pains to train actors in the rôle of "casualties," and to make them look the part; the autumn number of the union's journal, for example, contains articles on the faking of flesh wounds and a formula for washable blood. It only remains for the casualty to be found in a realistic environment—on the road, pinned under a beam, or in a smoke-filled room—and the stage is set for a first-class exercise. The aims of the union, whose branches are multiplying in the home counties, will be applauded by all who are interested in better first-aid. The hon. secretary's address is The Bend, Send, Surrey.

University of Cambridge

An election to the Pinsent-Darwin studentship in mental pathology will be made next March. The studentship has an annual value of not less than £225 and is tenable for three years. Applications should be submitted, before Feb. 28, to the secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge.

University of Sheffield

Dr. Quentin Gibson has been appointed lecturer in physiology in the university.

Royal College of Physicians

Prof. F. C. Bartlett, F.R.S., will deliver the Oliver-Sharpey lectures at 5 P.M. on Tuesday, Jan. 21, and Thursday, Jan. 23. His subject will be the Measurement of Human Skill.

University of Edinburgh

On Dec. 13 the following degrees were conferred :

M.D.—M. W. Archdall, *L. F. Brown, *E. M. Donaldson, *Jack Greenstein, *A. F. Lang, Tormod Macleod, *I. R. Milne, R. W. G. Ransome-Wallis, †G. D. F. Steele.

M.D. of the Polish School.—A. J. Baranski, J. F. Majeranowski.

M.B., Ch.B.—H. I. O. Armstrong, G. H. Blair, John Calder, G. R. Duffes, J. T. Y. Forrest, Mary G. Forsyth, G. R. C. D. Gibson, A. C. Jacob, Muriel G. James, D. L. Kirk, W. H. Lloyd, J. M. Loughran, N. C. Low, Alexander MacLennan, Jean C. I. Melville, Catherine S. Paterson, J. P. Payne, J. C. Phemister, Kenneth Robertson, C. M. C. Smelt, Anne M. Stewart, I. C. Wilson, J. H. Young.

M.B., Ch.B. of the Polish School.—Bohdan Adamski, Stefan Dyakowski, Mojzesz Gonszor, Adam Jarosz, Antoni Kepinski, Jerzy Klimczynski, Tadeusz Klosowski, J. K. Koziol, J. G. Lipski, Wladyslaw Mitus, Zbigniew Prokopowicz, Anna M. Sokolowska, Mieczyslaw Szamocki, Zdzislaw Teleszynski, Józef Wilczynski, Hanna H. Wozniak, Stefan Wozniak, Witold Zaleski, Wladyslaw Zarski.

* Commended. † Highly commended.

Royal College of Surgeons of England

At an ordinary meeting of the council on Dec. 12, with Sir Alfred Webb-Johnson, the president, in the chair, Mr. R. M. Handfield-Jones, St. Mary's Hospital, was admitted as a member of the court of examiners. Prof. Ian Aird, F.R.C.S.E., British Postgraduate Medical School, was admitted ad eundem to the fellowship.

The Hallett prize was presented to Mr. R. P. Melville (Sydney). Mr. J. G. Turner and Prof. Evelyn Sprawson were elected Charles Tomes lecturers for 1947. Mr. P. H. Mitchiner was appointed editor of the forthcoming college publication.

A gift of 50,000 francs towards the restoration fund was received from the Association française de Chirurgie.

A diploma of membership was granted to E. N. Rees.

Diplomas of fellowship were granted to the following candidates :

A. G. Tresidder, John Penry, D. B. Cater, Thomas Denness, W. G. France, J. A. R. Johnson, C. M. Dransfield, M. A. Margo, J. W. M. Leslie, J. A. Rhind, W. D. Doey, K. H. Taylor, J. A. S. Green, C. A. Jackson, R. G. Robinson, D. H. Thompson, T. H. Cullen, J. S. McConnachie, K. W. Martin, A. J. Walker, F. H. D. Hutter, G. K. Rose, G. E. Stein, L. R. S. Taylor, C E. Drew, H. H. G. Eastcott, Arsen Klidjian, P. C. Watson, T. L. Kennedy, H. W. A. Baron, Ambrose Jolleys, C. O. Fung-Kee-Fung, A. M. Wood, L. L. Bromley, I. A. Alexander, A. H. M. H. Ashoor, C. H. Bartlett, S. K. Burcher, Mortimer Burdman, H. A. Daniels, J. B. Dowe, H. B. Hattam, L. H. Hiranandani, E. S. R. Hughes, Hassan Ibrahim, D. S. Iyer, D. R. Leslie, John Loewenthal, S. D. Loxton, A. B. McCarten, R. J. Manekshe, Raphael Marcus, K. W. Priddis, J. G. Pyper, R. F. Read, W. S. Rees, D. B. Robertson, D. R. Ryder, V. S. Sheth, F. N Street, J. M. Tyler, S. A. Vincent, Muriel C. Waterfall, T. E. Wilson.

Diplomas in anæsthetics were granted jointly with the Royal College of Physicians to the following candidates :

E. F. Adams, S. N. Albert, G. S. Ambardekar, J. D. M. Barton, W. L. Bilsland, R. P. Bliss, N. H. Bloom, R. A. Bowen, D. M. Brown, C. A. Cheatle, H. C. Churchill-Davidson, R. E. W. B. Comerford, R. L. Coulter, J. I. Davies, W. W. Deane, A. G. Doughty, G. L. Evans, Henry Fairlie, D. J. H. Goodhew, Helen E. Gordon, R. W. G. Grindlay, J. R. Hamerton, Godfrey Herington, M. H. W. Holloway, Gordan Houseman, M. S. Howe, J. McN. Inglis, R. G. G. Jones, W. A. Jones, F. M. Lancaster, R. A. Lattey, J. D. Loughrey, T. H. McCall, I. M. McCully, A. I. MacKenzie, Leonard Mather, Julia M. Middleton, Michael Nash, James North, J. R. Odell, H. F. Patrick, A. W. Raffan, G. A. Rawlins, D. F. Rees, G. J. Rees, T. B. L. Roberts, Eleanor H. Russell, L. T. Scott, J. J. Slowe, James Straton, E. I. Tate, W. N. Vellacott, G. L Way, J. H. Willis, F. G. Wood-Smith, D. S. Young.

Royal College of Physicians of Edinburgh

At a meeting of the college held on Dec. 5 Dr. D. M. Lyon was re-elected president. Dr. W. D. D. Small, Dr. L. S. P. Davidson, Dr. J. D. S. Cameron, Dr. H. L. Wallace, Dr. I. G. W. Hill, and Dr. D. K. Henderson were elected to form the council for the ensuing year. Dr. W. D. D. Small was nominated vice-president.

Ophthalmological Society of the United Kingdom

The society's annual congress will be held in Glasgow from March 27 to 29. Rhinology in Relation to Ophthalmology is among the subjects for discussion. The hon. secretary for the congress is Mr. E. F. King, 79, Harley Street, London, W.1.

Cancer Instruction in the United States

A committee of 24 doctors, representing 14 medical schools, has been formed, under the chairmanship of Prof. Frank E. Adair, to advise the National Advisory Cancer Council on the place of cancer in the medical curriculum. The aim is to make courses on the subject more comprehensive and better integrated.

University College Hospital Medical School

The centenary of the first public administration of Europe is to be commemorated in a lecture by Dr. Dawkins on Saturday, Dec. 21, at 4.45 P.M.

British Institute of Radiology

A series of six lectures on the Applications of Physics in Medicine will be given by Prof. W. V. May at the institute at 5 P.M. on successive Wednesdays, Jan. 1.

Prospects for Reablement

Opening a new rehabilitation and occupational centre at Bromley Hospital on Dec. 14, Sir Wilson chief medical officer of the Ministry of Health, said is a need for still more centres, whose staff should inclu almoner or social worker, to coöperate with the Minis Labour's disablement resettlement officer and the empl the general practitioner, *too, must be kept informe* future medical students may receive fuller instructi physiotherapy and reablement. The idea of g practitioner hospitals, linked to larger institutions, h concluded, now been accepted.

Maudsley Hospital Postgraduate Medical School

A course, in two parts, for the diploma in psychol medicine, will be given at the school in the New Year. first part, in January and February, will be concerne the anatomy and physiology of the *nervous* system, e encephalography, biochemistry in relation to the n system, physiological psychology, psychology, and m psychology. The second part, from March to June include lectures on psychiatry, psychopathology, and p therapy, and related biochemical, pathological, genetic, legal, and social questions. Six months' instruction in psychiatry is included, and there w twenty clinical demonstrations in neurology. Applicati enrolment should be made to the dean, 107, Denmarl London, S.E.5.

Call for Blood-donors

Over 12,000 new donors joined the blood-transfusion in the three months up to Oct. 1 ; but nearly 150,000 volunteers are needed. *It is estimated that* 400,000 donations will be *required in* 1947.

Return to *Practice*

The Central Medical War Committee announces th *following have resumed civilian practice :*

Dr. BYRON EVANS, 59, Cathedral Road, Cardiff (Cardiff 938
Dr. F. BASIL KIERNANDER, 78, Wimpole Street, W.1 (W 8874), and 7, Henley Avenue, Iffley, Oxford (Oxford 721

The headquarters and London regional offices c Central Council of Physical Recreation are now at 6, B Square, W.C.2.

Appointments

CASSON, F. R. C., M.B. Lond., D.P.M. : clinical assistant, depa of psychological medicine, National Hospital for N Diseases, Queen Square.

GORDON, ISRAEL, M.D. Edin., M.R.C.P., D.P.H. : deputy Ilford.

GREEN, S. I., M.B. Lond., F.R.C.S. : surgical registrar, King's Hospital, London.

MCKENZIE, PETER, M.B. Glasg., D.P.H. : deputy physician-intendent, City of Glasgow Fever Hospital.

ROBINSON, W. L., M.B. Belf. : resident surgeon, St. Vincent, ward Islands, Colonial Service.

ROSS, G. L. M., M.B Aberd., F.R.C S. : medical officer, Gil Colonial Service.

STENT, LOIS, M.D. Manc., D.BACT. : pathologist, With Hospital.

STRANG, R. A., M.B. Glasg., D.P.H. : deputy M.O.H., Harrow

Purley and District War Memorial Hospital :

GREIG, D. L., M.R.C.S., D.M.R.E. : radiologist.
WARREN, C. P., M.B. Lond., D.C.P. : pathologist.

Royal Infirmary, Sunderland :

COWAN, I. C., B.SC., M.B. Aberd. : M O. i/c of physical medi
KNOWLES, E. W., M.CH. ORTH. Lpool, F.R.C S. : assistant pædic surgeon.
LEVY, H. B. M., M.C., M.S. Durh. F.R.C.S I. : surgeon.
LOWDEN, T. G., B.M. Oxfd, F.R.C.S. : assistant surgeon.
ROSS, J. M. H., M.B. Edin , F.R.C.S.E. : assistant surgeon.
SANFORD, D. A., M.B. Lond., F.R.C.S , M R.C.P. : surgeon.
WEIR, J. A., M.B. Glasg., F.R.C.S.E. : assistant surgeon.

Examining Factory Surgeons :

DAVID, G. E., M.R.C.S. : Ystalyfera, Glam.
DEWHURST, M. S., M.B. Camb. : Havant, Hants.
MCCALLUM, STEWART, L.R.C.P.E. : Leek, Staffs.

PALINDROMIC RHEUMATISM[*]

F. PARKES WEBER
M.D. Camb., F.R.C P.

PALINDROMIC rheumatism is a convenient term for some clinical syndromes of uncertain causation and for component parts of more complicated "compound" syndromes.

Hench and Rosenberg (1944) described thirty-four cases of a "new" recurrent disease of joints and adjacent tissues: multiple afebrile attacks of acute arthritis and periarthritis. In some cases there were also recurring para-arthritic swellings of soft tissues in the neighbourhood, including in a few patients small temporary intracutaneous or subcutaneous nodules. The attacks developed suddenly, generally lasting only a few hours or days, but recurring repeatedly at short or long *irregularly* spaced intervals. They were manifested by pain, swelling, redness, and disability of one (sometimes more than one) small or large joint. Little or no constitutional reaction or abnormality was revealed by laboratory tests; and no significant functional, pathological, or radiographic evidence of disease was found even after scores of attacks, in spite of the transitory presence (in some cases at least) of an acute or subacute inflammatory polymorph exudate in the articular tissues and cavity.

The incidence was about equal in the two sexes. The patients on admission were aged 21–73 (average 42). The age at onset of the disease was 13–68 (average 34·9). The recurrence notably changed its frequency in four patients. The intervals between attacks differed materially in different cases and from time to time in the same case. As already mentioned, usually only one joint was involved in an attack. Almost any joint in the body was liable to be affected. Finger-joints (notably proximal interphalangeal joints) were especially frequently involved, and then, in order of frequency, came wrists, shoulders, knees, toes, and elbows. Tendon sheaths were also occasionally affected by sudden similar attacks.

TERMINOLOGY

Hench and Rosenberg (1944), who introduced the name "palindromic rheumatism," point out that "palindromic" is simply Greek for "recurrent," and they prefer the relatively vague and non-committal word[†] "rheumatism" (as in frequent medical and popular use) to the more exact word "arthritis." Indeed, the symptoms are not absolutely limited to the joints, for there are sometimes pararthritic (para-arthritic or para-articular) swellings and nodules, and the tendon-sheaths—and sometimes bursæ, notably the olecranon bursa (see below)—may be involved.

It seems to me that the term "palindromic rheumatism" might well be used in a wider sense, to include attacks of intermittent or recurrent hydrarthrosis (whether strictly periodic or not), as described by Schlesinger (1899), Garrod (1910), and many others; the term might also be used for some at least of the cases described by Solis-Cohen (1914) in his paper on "angioneural arthroses commonly mistaken for gout or rheumatism," and for Kahlmeter's (1939) attacks of allergic (?) rheumatism. One may note, by the way, that the curious recurrent attacks described under the heading "urticaria tuberosa of Willan" (Nixon 1916) have analogies with angioneurotic œdema and para-articular phenomena of intermittent hydrarthrosis and palindromic rheumatism.

It is true that some of Solis-Cohen's cases were febrile, whereas the attacks in Hench and Rosenberg's patients were afebrile, as were most of the intermittent hydrarthrosis attacks referred to by Garrod and others. Most of the cases of intermittent hydrarthrosis were definitely periodic, whereas the intervals between the attacks in Hench and Rosenberg's cases were irregular. Though the differences between these various classes may be considerable, enough perhaps to separate them roughly into various clinical syndromes, the points of resemblance are, I think, sufficiently marked to justify their collection into various syndrome-groups under one heading, "palindromic rheumatism."

ÆTIOLOGY

Can there be any common ætiological factor in all these cases? There is some resemblance between individual attacks of "palindromic rheumatism" and the acknowledged allergic joint symptoms of "serum disease." Many have noted an analogy with angioneurotic œdema, which a few of the patients also had. Schlesinger (1899) was struck by resemblances between angioneurotic œdema and intermittent hydrarthrosis, and suggested that some cases of intermittent hydrarthrosis were really angioneurotic œdema of synovial membrane. In the families of some patients with palindromic rheumatism (in my enlarged sense) there have been allergic manifestations, such as urticaria, angioneurotic œdema, asthma, and, I think, recurrent vomiting. Apart from allergy in family history, it may be noted that some of Kahlmeter's (1939) patients had urticaria, angioneurotic œdema, asthma, or migraine. It must be admitted that palindromic rheumatism (in my wider and more inclusive sense) is intimately allied to allergy or some process resembling allergy, even if no causal allergens for the attacks have yet been discovered. Focal sepsis has probably been a causal factor in some cases, owing to bacterial allergens being discharged at times into the blood-stream. One may suspect an inborn tendency as a factor in a few cases in which a family history of similar attacks and acknowledged allergic conditions was forthcoming. Frenkel-Tissot (1916) reported that in a group of four sibs, three had had intermittent hydrarthrosis (knee), and the other was subject to periodic attacks of migraine and occasional urticaria.

SYMPTOMS

Garrod (1910) agreed with previous writers in dividing cases of intermittent hydrarthrosis into primary and symptomatic cases:

> "In primary cases the periodic swelling comes on as an isolated event, sometimes after an injury; and the affected joints, which are in the great majority of instances the knees, recover completely or almost completely in the intervals, at any rate in the earlier stages. In symptomatic cases, on the other hand, the affected joints have already been damaged, more or less severely, by antecedent disease, such as the more obstinate forms of gonorrhœal arthritis, or the crippling lesions of many joints commonly classed as rheumatoid arthritis or arthritis deformans. In other respects the cases of the two classes closely resemble each other, and the observation of a series of examples inclines one to the opinion that, as Linberger (1901) maintains, intermittent hydrarthrosis is a phase or symptom of various diseases rather than a disease sui generis."

A woman, aged 67, in hospital at present with old osteo-arthritis and pernicious anæmia, was under my care about 1919 (when she was aged 40) with recurrent, but not periodic, attacks of swelling, stiffness, and pain in the left knee, each attack lasting a few days. The radiologist (Dr. James Metcalfe) suggested "intermittent synovitis."

Garrod (1910) draws attention to abrupt changes in the features sometimes seen, possibly in connexion with therapeutic measures, when the intermittent hydrarthrosis ceases and is resumed after a more or less long pause. The frequency may change, or the attacks may recur on the opposite side of the body. I was once shown an excellent example of such a change (a case of Dr. O. B. Bode). Of concurrent conditions, Garrod writes, pregnancy exercises the most conspicuous influence on the course of intermittent hydrarthrosis. In most recorded instances the articular attacks have ceased during pregnancy, but not always throughout the whole period of pregnancy. In certain cases hydrarthrosis attacks have shown relation to menstrual periods. Attacks have been more severe or less severe when they coincided with menstrual periods.

---

[*] Part of the annual oration at the Reading Pathological Society, Oct. 24, 1946.

[†] Many terms in medical as well as popular use are somewhat vague and, strictly speaking, inexact Thus the term "aortic coarctation" is often used by medical writers to mean stenosis of the aortic isthmus, though it strictly signifies nothing more than aortic stenosis (stenosis of the aortic valves and orifice).

The small temporary pararthritic intracutaneous and subcutaneous nodules, investigated by Hench and Rosenberg in some of their cases, remind me of the little nodules which sometimes suddenly develop and spontaneously disappear in cases of rheumatoid arthritis, and which may represent an early stage of the well-known "chronic necrobiotic subcutaneous nodules of the rheumatoid arthritis type" (Weber 1946), though they become reabsorbed without the development of necrotic foci.

SOME MORE COMPLICATED "COMPOUND" SYNDROMES

Palindromic rheumatism, in my proposed extended sense, is also a convenient term for prominent features of certain more complicated syndromes, which are probably almost unique. I will give two examples.

The first case can be described as one of palindromic rheumatism without permanent changes in or round affected joints; with recurrent (allergic ?) attacks of Ménière's syndrome, without resulting deafness; and with recurrent (allergic ?) attacks of iritis, with pain but without permanent synechiæ or permanent changes in the eyes.

CASE 1.—A man, aged 28, with the above-mentioned complaints, was admitted to hospital on August 6, 1946, for investigation. He had been born in Burma of British parents, and had been married one year—no children.

History.—Seventeen years ago he had begun to have attacks of pain in the hip-joints, especially the right one. The pain had been felt in the joints (rather than about the joints or in the bones), sometimes radiating down the thigh from the affected hip-joint. The pain had been boring and especially sharp on moving. Besides the pain there had been a sensation of stiffness. No local tenderness; no definite periodicity, but on the average about six months' interval between attacks, which had lasted usually a few weeks. Nothing abnormal had been detected on radiography. The attacks had apparently been afebrile and not accompanied by constitutional symptoms. No definite diagnosis seems to have been made. Rest in bed for five months had been at first ordered, but had been followed by no obvious improvement. Rest had therefore not been regularly adopted for treatment. The pain had usually been in the right hip-joint, but sometimes in the left. Both sides had never been affected together. No other joints had ever been involved. Last attack had been about three weeks ago, right more than left hip. Both hip-joints had been affected, but one side had been completely free (after two weeks) before the other had become painful (for a week). Patient does not go to bed for the attacks, though occasionally owing to the pain he has had to rest.

The attacks of *Ménière's syndrome* had never come on at the same time as the joint-pains. The first sharp attack had been twelve years ago, accompanied by vomiting. Patient had woken up one morning unable to sit up or turn over in bed; he had vomited four or five times, but the vomiting had not been accompanied by a sensation of nausea; that attack had lasted thirty-six hours. The next attack had been a few months later. The interval between attacks had varied from a few months to two years up to three or four years ago; but since then the attacks had been more frequent though less severe, excepting for one severe (the last) attack six weeks ago. The average duration of the attacks had been 24–30 hours, but they might last up to three days. No causal factors had been discovered. Prodromal symptoms had been a kind of light-headedness and tinnitus, slight at first b becoming more pronounced as the attack gradually develop There had been no associated deafness either during or af the attacks—hearing not impaired. No associated headach no associated incontinence. Of the vertigo, patient said th his surroundings seemed at first to revolve; but, when h lay down, objects seemed to pass back over his vertex fro the front. The attacks appeared to be relieved by lying fl on the back—? aborted by pilocarpine gr. $^1/_{10}$.

Seven years ago he had developed the first of seven or eigh attacks of *iritis.* That attack had been on the right side an had lasted about eight weeks. Patient had had only on attack on the left side; the two sides had never been affecte simultaneously. The attacks had been accompanied by considerable eye-pain, especially on coming into the light from dark room. They had occurred at about yearly intervals average duration about a month. They had varied in intensit No precipitating factor known. The last attack had bee in January, 1946.

The eye, ear, and joint attacks had never accompanied on another; not more than one of the three kinds had occurre at a time.

Patient's *general health* apart from the above troubles ha been good, and there had been no other serious complain There was nothing in the family history specially bearing o the subject. We heard privately that the family was "delicate.' A sister had recently had pericarditis after "sinusitis" a the age of 23. Patient's mother had died young; caus uncertain. Patient had seen various specialists. A salt-fre diet had not helped. Dr. Norman William Gardener ha always treated patient for his eyes—with atropine ointmen and by "steaming." Dr. Gardener is certain that the ey attacks were definitely iritis, possibly tuberculous. There ha been definite iritic exudate (plastic iritis) but no permanen synechiæ. This iritis had affected only one eye at a tim He cannot remember whether there had been any sluggishnes in pupillary reaction, change in colour of the affected iris, o any inequality of pupils before atropine treatment had bee begun.

On Admission to Hospital.—Height 5 ft. $6^1/_2$ in.; weigh 8 st. 12 lb. Tall, hyposthenic type, rather delicate-looking No evidence of anæmia. Teeth, tongue, tonsils, and throat nothing special. No obvious enlargement of any superficia lymph-glands. No evidence of latent tetany. Cardiovascula system: nil special. Brachial blood-pressure 135/80 mm. Hg Respiratory system: nil special. Abdomen: nil special. N achlorhydria (August 10, 1946). Central nervous system: nil special. Eyes: very slight lateral nystagmus; slight myopia Hearing good on both sides. Nervous reflexes (deep and superficial) normal. Urine: acid; trace albumin; a few hyaline casts. But on another occasion nothing abnormal was found; sp. gr. 1020, acid. No other abnormal urinary symptoms. Radiograms of both hip-joints and of skull (Dr. F. G. Wood, August 6, 1946): nothing abnormal. Blood Wassermann reaction negative (July 17, 1946). Blood-sugar 110 mg. per 100 c.cm. Blood-uric acid (August 10, 1946) 3·2 mg. per 100 c.cm. Sedimentation-rate (August 7, 1946): first hour 6 mm.; two hours 17 mm. (hourly average 7 mm.). Blood-count (August 17, 1946): red cells 4,950,000 per c.mm.; Hb 96%; colour-index 0·97; leucocytes 7000 per c.mm. On August 21, 1946, the leucocytes were 7900 per c.mm. (polymorphs 76%, lymphocytes 23%, eosinophils 1%).

Patient is now under observation at home, apparently at present in good health.

The symptoms in this case are clearly enough defined to constitute a definite triad syndrome, but no other exactly similar case seems to be known. It is difficult to avoid the conclusion that each of the three syndromes constituting this compound triad syndrome is allergic, though no focal sepsis or allergen has been discovered.

Quincke (1921), among the numerous unusual localisations of his angioneurotic œdema, does not seem to have mentioned the internal ear and Ménière's syndrome. Duke (1923) suggested an allergic origin for some cases of Ménière's syndrome. He referred to a man and a woman with definite allergic history in whom Ménière's attacks seem to be caused by certain articles of food. The attacks were relieved by adrenaline and by the voidance of the foods in question; attacks could be produced by eating such foods, or by intracutaneous jection of extracts. Williams (1945, 1946) has recently laborated an allergic explanation, linking Ménière's isease or, rather, syndrome—which he terms endo-mphatic hydrops of the ear—with vasomotor rhinitis, c., as manifestations of "physical allergy" in he head.

In regard to the recurrent attacks of iritis, I think hey are most probably also allergic. Though I know f allergic cataract (so-called dermatological cataract) ccurring in subjects with allergic dermatoses (eczema-rurigo syndrome, with or without asthma, névro-lermite), and of allergic conjunctivitis—e.g., that ssociated with hay-fever—there is apparently no phthalmological literature recording recurrent iritis as n this patient (compare Ridley and Sorsby 1940). If he patient's joint attacks had been "real" (? strepto-occal) rheumatism instead of palindromic rheumatism, he attacks of iritis might have been supposed to be heumatic iritis, and therefore allergic in so far as acute heumatism is now generally supposed to represent an llergic response towards the pathogenic agent of acute heumatism (? some hæmolytic streptococcus or virus). t may be noted, however, that Parry (1939) recorded ecurrent attacks of iridocyclitis in a young woman, pparently allergic and due to hypersensitivity to egg-white.

In short, this case strongly supports Schlesinger's original views of 1899, according to which the condition would be angioneurotic œdema or, as he preferred to call it, hydrops hypostrophos—i.e., recurrent œdema—sometimes of the synovial membrane of a hip-joint, sometimes of one iris, and at other times of one internal ear, the cochlea beginning to be affected before the semicircular canals. The iris attacks, it must be admitted, are rather chronic, but doubtless in some localisations angioneurotic œdema may be relatively chronic. An allergic reaction may doubtless be chronic if there is ersistent action of some known or unknown allergen in an allergic subject. Recurrent acute reactions can give rise to chronic (persistent) changes. I believe that Loeffler's "transitory pulmonary infiltrations with eosinophilia" are nothing else than angioneurotic œdema, but apparently attacks are not always quite so transitory —compare the case of a man, aged 19, with a history of hay-fever, shown by A. Elkeles and N. R. Butler at the Clinical Section of the Royal Society of Medicine on April 12, 1946, as an example of "recurrent transitory pulmonary infiltrations with eosinophilia (chronic type of Loeffler's syndrome)."

The second case is one which the late Lord Dawson discussed with me in 1942 as a puzzling rarity.

CASE 2.—The patient was a tall strong-looking man, aged about 60, who since 1936 had had attacks of swellings of the hands or feet, usually only one side at a time. The forearms, knees, and legs had been similarly affected. Sometimes also there had been sudden enlargement of an olecranon bursa (no evidence of gout discovered). There had also been subcutaneous nodules along the ridge of the ulna from the elbow; these had been situated over the periosteum and not in it, though somewhat adherent to it. Sensation of tightness in an arm, leg, or shoulder had sometimes given warning of an impending attack. The attacks had never been accompanied by fever or definite pain (contrast this with true attacks of gout). The attacks had lasted a few days and slowly passed off.

I saw him during one attack, which was of three or four days' duration and was beginning to subside. Some fingers of both hands were involved, in one hand more than in the other. The skin over the swelling was red and shiny in some parts, but some patches or streaks were pale, as if blood had been driven out of the surface capillaries by the pressure of serous effusion. Patient had also a chronic smooth bony enlargement (not painful or tender) of the upper end of one fibula, which is difficult to explain.

Previous Data.—A symptomless stone in the gall-bladder had been discovered on routine radiography. Liver efficiency was normal. Gastric achlorhydria was reported, but some free acid returned after gastric lavage. Blood-uric acid 3·6 mg. per 100 c.cm. Blood-sugar normal. Radiography showed no articular changes and nothing abnormal in the bones, but the swelling in the fibula had apparently not been examined. Brachial systolic blood-pressure about 130 mm. Hg.

On one occasion an enlarged olecranon bursa had been tapped and had yielded a serous fluid, giving a pure culture of *Staph. aureus*. No definite evidence of allergy had been discovered by skin tests. One antrum was opaque and had been cleared and curetted for a polypoid condition, but that had had no effect on patient's "attack." A pure growth of *Staph. aureus* had been obtained from the antrum. 'Atophan' had seemed to diminish the attacks at first, but not later.

The attacks had never laid the patient up, but if his fingers had been much swollen during an attack he could hardly use them, and could not write. He took an ordinary diet, as he had found that diet made no difference. He had also left off taking dilute hydrochloric acid with meals, as he thought that also had made no difference. While he had been in South Africa he had remained free from attacks; but, after he had left, they had begun again. Exposure to cold had sometimes definitely brought on an attack.

This case seems to come half-way between palindromic rheumatism and angioneurotic œdema. According to Schlesinger's views of 1899 the patient would be suffering from recurrent angioneurotic œdema (or hydrops hypostrophos, as he called it) of the peri- and para-arthritic tissues of his fingers and limbs and notably sometimes of the synovial lining and wall of one of his olecranon bursæ. The appearance of subcutaneous nodules over the ulnar ridge from the elbow downwards, as in some cases of rheumatoid arthritis, is a feature of the case (cf. Weber 1946). The swelling of the upper end of one fibula is unexplained.

SUMMARY

In spite of obvious objections which might be raised by the fastidious in nomenclature, it is convenient to retain the rather loose term "palindromic rheumatism" proposed by Hench and Rosenberg (1944). Perhaps, however, it would be better to enlarge the scope of the term, to include nearly related syndromes, such as intermittent hydrarthrosis (hydrops articulorum intermittens), which Schlesinger (1899) suggested was a recurrent angioneurotic œdema (hydrops hypostrophos he termed it) of the synovial membrane and soft parts *of joints*.

Palindromic rheumatism, in the extended sense that I propose, constitutes also a convenient term for the central features of certain more complicated ("compound") syndromes, two remarkable examples of which are described.

I am indebted to Dr. E. Schwarz for permission to publish the record of case 1.

Postscript.—An elderly medical friend told me of his recent experience. He had a slight "cold" accompanied by cough and slight sore throat. About a week later he was suddenly attacked by sharp pain and swelling therapeutic measures, when the intermittent hydrarthrosis ceases and is resumed after a more or less long pause. The frequency may change, or the attacks may recur on the opposite side of the body. I was once shown an excellent example of such a change (a case of Dr. O. B. Bode). Of concurrent conditions, Garrod writes, pregnancy exercises the most conspicuous influence on the course of intermittent hydrarthrosis. In most recorded instances the articular attacks have ceased during pregnancy, but not always throughout the whole period of pregnancy. In certain cases hydrarthrosis attacks have shown relation to menstrual periods. Attacks have been more severe or less severe when they coincided with menstrual periods.

The small temporary pararthritic intracutaneous and subcutaneous nodules, investigated by Hench and Rosenberg in some of their cases, remind me of the little nodules which sometimes suddenly develop and spontaneously disappear in cases of rheumatoid arthritis, and which may represent an early stage of the well-known "chronic necrobiotic subcutaneous nodules of the rheumatoid arthritis type" (Weber 1946), though they become reabsorbed without the development of necrotic foci.

SOME MORE COMPLICATED "COMPOUND" SYNDROMES

Palindromic rheumatism, in my proposed extended sense, is also a convenient term for prominent features of certain more complicated syndromes, which are probably almost unique. I will give two examples.

The first case can be described as one of palindromic rheumatism without permanent changes in or round affected joints; with recurrent (allergic ?) attacks of Ménière's syndrome, without resulting deafness; and with recurrent (allergic ?) attacks of iritis, with pain but without permanent synechiæ or permanent changes in the eyes.

CASE 1.—A man, aged 28, with the above-mentioned complaints, was admitted to hospital on August 6, 1946, for investigation. He had been born in Burma of British parents, and had been married one year—no children.

History.—Seventeen years ago he had begun to have attacks of pain in the hip-joints, especially the right one. The pain had been felt in the joints (rather than about the joints or in the bones), sometimes radiating down the thigh from the affected hip-joint. The pain had been boring and especially sharp on moving. Besides the pain there had been a sensation of stiffness. No local tenderness; no definite periodicity, but on the average about six months' interval between attacks, which had lasted usually a few weeks. Nothing abnormal had been detected on radiography. The attacks had apparently been afebrile and not accompanied by constitutional symptoms. No definite diagnosis seems to have been made. Rest in bed for five months had been at first ordered, but had been followed by no obvious improvement. Rest had therefore not been regularly adopted for treatment. The pain had usually been in the right hip-joint, but sometimes in the left. Both sides had never been affected together. No other joints had ever been involved. Last attack had been about three weeks ago, right more than left hip. Both hip-joints had been affected, but one side had been completely free (after two weeks) before the other had become painful (for a week). Patient does not go to bed for the attacks, though occasionally owing to the pain he has had to rest.

The attacks of *Ménière's syndrome* had never come on at the same time as the joint-pains. The first sharp attack had been twelve years ago, accompanied by vomiting. Patient had woken up one morning unable to sit up or turn over in bed; he had vomited four or five times, but the vomiting had not been accompanied by a sensation of nausea; that attack had lasted thirty-six hours. The next attack had been a few months later. The interval between attacks had varied from a few months to two years up to three or four years ago; but since then the attacks had been more frequent though less severe, excepting for one severe (the last) attack six weeks ago. The average duration of the attacks had been 24–30 hours, but they might last up to three days. No causal factors had been discovered. Prodromal symptoms had been a kind of light-headedness and tinnitus, slight at first but becoming more pronounced as the attack gradually developed. There had been no associated deafness either during or after the attacks—hearing not impaired. No associated headache; no associated incontinence. Of the vertigo, patient said that his surroundings seemed at first to revolve; but, when he lay down, objects seemed to pass back over his vertex from the front. The attacks appeared to be relieved by lying flat on the back—? aborted by pilocarpine gr. $^1/_{10}$.

Seven years ago he had developed the first of seven or eight attacks of *iritis*. That attack had been on the right side and had lasted about eight weeks. Patient had had only one attack on the left side; the two sides had never been affected simultaneously. The attacks had been accompanied by considerable eye-pain, especially on coming into the light from a dark room. They had occurred at about yearly intervals; average duration about a month. They had varied in intensity. No precipitating factor known. The last attack had been in January, 1946.

The eye, ear, and joint attacks had never accompanied one another; not more than one of the three kinds had occurred at a time.

Patient's *general health* apart from the above troubles had been good, and there had been no other serious complaint. *There was nothing in the family history specially bearing on the subject.* We heard privately that the family was "delicate." A sister had recently had pericarditis after "sinusitis" at the age of 23. Patient's mother had died young; cause uncertain. Patient had seen various specialists. A salt-free diet had not helped. Dr. Norman William Gardener had always treated patient for his eyes—with atropine ointment and by "steaming." Dr. Gardener is certain that the eye attacks were definitely iritis, possibly tuberculous. There had been definite iritic exudate (plastic iritis) but *no permanent* synechiæ. This iritis had affected only one eye at a time. He cannot remember whether there had been any sluggishness in pupillary reaction, change in colour of the affected iris, or any inequality of pupils before atropine treatment had been begun.

On Admission to Hospital.—Height 5 ft. $6^1/_2$ in.; weight 8 st. 12 lb. Tall, hyposthenic type, rather delicate-looking. No evidence of anæmia. Teeth, tongue, tonsils, and throat: nothing special. No obvious enlargement of any superficial lymph-glands. No evidence of latent tetany. Cardiovascular system: nil special. Brachial blood-pressure 135/80 mm. Hg. Respiratory system: nil special. Abdomen: nil special. No achlorhydria (August 10, 1946). Central nervous system: nil special. Eyes: very slight lateral nystagmus; slight myopia. Hearing good on both sides. Nervous reflexes (deep and superficial) normal. Urine: acid; trace albumin; a few hyaline casts. But on another occasion nothing abnormal was found; sp. gr. 1020, acid. No other abnormal urinary symptoms. Radiograms of both hip-joints and of skull (Dr. F. G. Wood, August 6, 1946): nothing abnormal. Blood Wassermann reaction negative (July 17, 1946). Blood-sugar 110 mg. per 100 c.cm. Blood-uric acid (August 16, 1946) 3·2 mg. per 100 c.cm. Sedimentation-rate (August 7, 1946): first hour 6 mm.; two hours 17 mm. (hourly average 7 mm.). Blood-count (August 17, 1946): red cells 4,950,000 per c.mm.; Hb 96%; colour-index 0·97; leucocytes 7000 per c.mm. On August 21, 1946, the leucocytes were 7900 per c.mm. (polymorphs 76%, lymphocytes 23%, eosinophils 1%).

Patient is now under observation at home, apparently at present in good health.

The symptoms in this case are clearly enough defined to constitute a definite triad syndrome, but no other exactly similar case seems to be known. It is difficult to avoid the conclusion that each of the three syndromes constituting this compound triad syndrome is allergic, though no focal sepsis or allergen has been discovered.

Quincke (1921), among the numerous unusual localisations of his angioneurotic œdema, does not seem to have mentioned the internal ear and Ménière's syndrome. Duke (1923) suggested an allergic origin for some cases of Ménière's syndrome. He referred to a man and a woman with definite allergic history in whom Ménière's attacks seem to be caused by certain articles of food. The attacks were relieved by adrenaline and by the roidance of the foods in question; attacks could be produced by eating such foods, or by intracutaneous jection of extracts. Williams (1945, 1946) has recently aborated an allergic explanation, linking Ménière's isease or, rather, syndrome—which he terms endo-mphatic hydrops of the ear—with vasomotor rhinitis, c., as manifestations of "physical allergy" in he head.

In regard to the recurrent attacks of iritis, I think hey are most probably also allergic. Though I know f allergic cataract (so-called dermatological cataract) ccurring in subjects with allergic dermatoses (eczema-rurigo syndrome, with or without asthma, névrolermite), and of allergic conjunctivitis—e.g., that ssociated with hay-fever—there is apparently no phthalmological literature recording recurrent iritis as n this patient (compare Ridley and Sorsby 1940). If he patient's joint attacks had been "real" (? streptococcal) rheumatism instead of palindromic rheumatism, he attacks of iritis might have been supposed to be heumatic iritis, and therefore allergic in so far as acute heumatism is now generally supposed to represent an llergic response towards the pathogenic agent of acute heumatism (? some hæmolytic streptococcus or virus). t may be noted, however, that Parry (1939) recorded ecurrent attacks of iridocyclitis in a young woman, pparently allergic and due to hypersensitivity to egg-white.

In short, this case strongly supports Schlesinger's riginal views of 1899, according to which the condition would be angioneurotic œdema or, as he preferred to all it, hydrops hypostrophos—i.e., recurrent œdema—sometimes of the synovial membrane of a hip-joint, ometimes of one iris, and at other times of one internal ar, the cochlea beginning to be affected before the emicircular canals. The iris attacks, it must be admitted, re rather chronic, but doubtless in some localisations angioneurotic œdema may be relatively chronic. An llergic reaction may doubtless be chronic if there is persistent action of some known or unknown allergen in an allergic subject. Recurrent acute reactions can give rise to chronic (persistent) changes. I believe that Loeffler's "transitory pulmonary infiltrations with eosinophilia" are nothing else than angioneurotic œdema, but apparently attacks are not always quite so transitory—compare the case of a man, aged 19, with a history of hay-fever, shown by A. Elkeles and N. R. Butler at the Clinical Section of the Royal Society of Medicine on April 12, 1946, as an example of "recurrent transitory pulmonary infiltrations with eosinophilia (chronic type of Loeffler's syndrome)."

The second case is one which the late Lord Dawson discussed with me in 1942 as a puzzling rarity.

CASE 2.—The patient was a tall strong-looking man, aged about 60, who since 1936 had had attacks of swellings of the hands or feet, usually only one side at a time The forearms, knees, and legs had been similarly affected. Sometimes also there had been sudden enlargement of an olecranon bursa (no evidence of gout discovered). There had also been subcutaneous nodules along the ridge of the ulna from the elbow; these had been situated over the periosteum and not in it, though somewhat adherent to it. Sensation of tightness in an arm, leg, or shoulder had sometimes given warning of an impending attack. The attacks had never been accompanied by fever or definite pain (contrast this with true attacks of gout). The attacks had lasted a few days and slowly passed off.

I saw him during one attack, which was of three or four days' duration and was beginning to subside. Some fingers of both hands were involved, in one hand more than in the other. The skin over the swelling was red and shiny in some parts, but some patches or streaks were pale, as if blood had been driven out of the surface capillaries by the pressure of serous effusion. Patient had also a chronic smooth bony enlargement (not painful or tender) of the upper end of one fibula, which is difficult to explain.

Previous Data.—A symptomless stone in the gall-bladder had been discovered on routine radiography. Liver efficiency was normal. Gastric achlorhydria was reported, but some free acid returned after gastric lavage. *Blood-uric acid* 3 6 mg. per 100 c.cm. Blood-sugar normal. Radiography showed no articular changes and nothing abnormal in the bones, but the swelling in the fibula had apparently not been examined. Brachial systolic blood-pressure about 130 mm. Hg.

On one occasion an enlarged olecranon bursa had been tapped and had yielded a serous fluid, giving a pure culture of *Staph. aureus*. No definite evidence of allergy had been discovered by skin tests. One antrum was opaque and had been cleared and curetted for a polypoid condition, but that had had no effect on patient's "attack." A pure growth of *Staph. aureus* had been obtained from the antrum. 'Atophan' had seemed to diminish the attacks at first, but not later.

The attacks had never laid the patient up, but if his fingers had been much swollen during an attack he could hardly use them, and could not write. He took an ordinary diet, as he had found that diet made no difference. He had also left off taking dilute hydrochloric acid with meals, as he thought that also had made no difference. While he had been in South Africa he had remained free from attacks; but, after he had left, they had begun again. Exposure to cold had sometimes definitely brought on an attack.

This case seems to come half-way between palindromic rheumatism and angioneurotic œdema. According to Schlesinger's views of 1899 the patient would be suffering from recurrent angioneurotic œdema (or hydrops hypostrophos, as he called it) of the peri- and para-arthritic tissues of his fingers and limbs and notably sometimes of the synovial lining and wall of one of his olecranon bursæ. The appearance of subcutaneous nodules over the ulnar ridge from the elbow downwards, as in some cases of rheumatoid arthritis, is a feature of the case (cf. Weber 1946). The swelling of the upper end of one fibula is unexplained.

SUMMARY

In spite of obvious objections which might be raised by the fastidious in nomenclature, it is convenient to retain the rather loose term "palindromic rheumatism" proposed by Hench and Rosenberg (1944). Perhaps, however, it would be better to enlarge the scope of the term, to include nearly related syndromes, such as intermittent hydrarthrosis (hydrops articulorum intermittens), which Schlesinger (1899) suggested was a recurrent angioneurotic œdema (hydrops hypostrophos he termed it) of the synovial membrane and soft parts of joints.

Palindromic rheumatism, in the extended sense that I propose, constitutes also a convenient term for the central features of certain more complicated ("compound") syndromes, two remarkable examples of which are described.

I am indebted to Dr. E. Schwarz for permission to publish the record of case 1.

Postscript.—An elderly medical friend told me of his recent experience. *He had a slight "cold" accompanied* by cough and slight sore throat. About a week later he was suddenly attacked by sharp pain and swelling in the left patellar bursa, accompanied by local heat and redness, with slight fever. He did not stop in bed, and in a week's time he felt quite well again. Then, however, he developed tenosynovitis about the left ankle, which gradually passed off. He had since early life been subject to migraine-like attacks, though not unilateral. With this exception he had enjoyed good health. As a young man he had had tenosynovitis in the wrist from fencing, and on the inner side of the knee when learning to ride. In this instance I suggest that the bursal swelling in front of the knee and the tenosynovitis were local allergic-like phenomena of the nature of angio-neurotic œdema. He may have become hypersensitive towards some "agent" introduced by the "cold."

Slight traumata may be supposed to act locally by causing the formation of some histamine-like substance, which *in hypersensitive subjects* produces a local œdematous inflammatory reaction and, if the process be frequently repeated, chronic fibrous thickening, as manifested in the permanently thickened bursa of "housemaid's knee," thickening of the olecranon bursa, and the chronic changes of Dupuytren's contraction and Landouzy's *acquired form of "camptodactylia."*

BODILY CHANGES DURING ABREACTION

ROBERT L. MOODY
M.B. Lond., D.P.M.
REGISTRAR, DEPARTMENT OF PSYCHOLOGICAL MEDICINE, GUY'S HOSPITAL; PSYCHIATRIST (E.M.S.), WOODSIDE HOSPITAL, LONDON

WHEN a traumatic experience is dissociated from normal consciousness it forms an unconscious emotionally charged complex. There is a natural tendency for such a complex to erupt into consciousness and, by so doing, to cause such symptoms as hysterical attacks and battle dreams. These symptoms are due to repetitions, more or less complete, of the original incident; and it is by such repetitions that the emotional charge is gradually dissipated until a point is reached where the experience becomes acceptable to consciousness and the symptoms subside. Often, however, spontaneous recovery does not occur, and the emotional charge has to be artificially reduced. This is usually done by abreaction under narcosis.

The essence of abreaction is that, with conscious control in abeyance, an uninhibited reliving of the traumatic incident can occur. It is found that the reliving process, once begun, proceeds automatically and is accompanied by full expression of the emotions and at least partial repetition of the bodily movements associated with the original incident. Thus it differs fundamentally from the mere recall of a forgotten event. Moreover, observation shows it to be, in many respects, an extraordinarily faithful repetition of the original incident. These complexes, therefore, may be described as psychosomatic experiences which, by reason of their being dissociated from normal consciousness, have remained in the unconscious, unchanged—like food that the stomach cannot digest. The result is that, when they reappear in consciousness, they may do so in toto in their original form, the experience of the body being repeated as well as that of the mind, at least in so far as the physiological mechanisms of the organism allow. These mechanisms are, however, much more extensive and specific in their field of operation than seems generally to be realised. I have therefore thought it worth while to make a full report of a case of localised specific somatic reaction, while referring to similar cases observed by myself and others to show that this is not a unique phenomenon.

CASE-RECORD

A man, aged 35, was admitted to hospital because of attacks of somnambulism accompanied by aggressive behaviour. He was a good type of Army officer who had had a upbringing in a stable middle-class family. He had nightmares in early childhood, but no instability had suspected by his relations until he had walked in his several times in his last year at a preparatory school. T condition had recurred at the age of 16, when he had been forcibly restrained. After leaving school he had joined th regular Army and gone abroad. Except for a few episodes he had remained well for some years. In 1935, however, he had been admitted to hospital with a minor condition and retained five months because of somnam which had recurred soon after his admission. As a result he had been invalided from the Service in 1936. He h remained nearly symptom-free until he had rejoined th Army in 1940.

During his detention in hospital in 1935 physical methods of various kinds had been used to restrain him. In his frequent nocturnal encounters with a bodyguard set to watch him he had sustained both physical and psychical traumata *while he was in a dissociated state.* These dissociated experiences had remained more or less latent for several years; but, as soon as treatment was undertaken, the strength of the repressive mechanism which had maintained that condition was undermined, and the automatic discharge of those experiences began—i.e., there was a recurrence of somnambulisms in whi he re-enacted (often in a truly alarming manner) the traumatic incidents he had experienced in hospital ten years previously. On one such occasion his hands had been tied behind his back during sleep, as a precautionary measure. Waking in a dissociated state to find himself thus constricted, he had struggled unsuccessfully to free himself. He then had managed to evade his bodyguard and had escaped into the surrounding countryside, from which he had returned a few hours later.

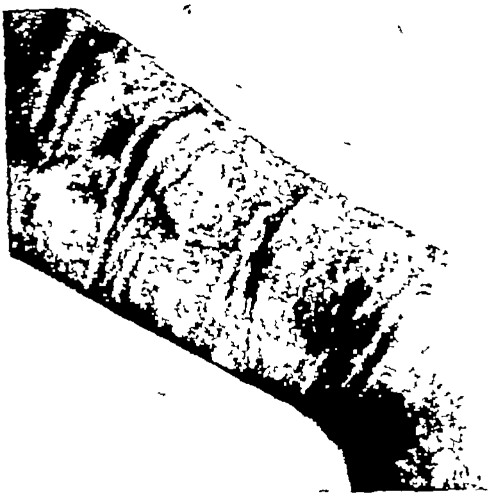
The following detailed account is given of the re-enactment of this incident:

On the night of April 9, 1944, the patient was observed by the nurse on duty to be tossing and turning violently on his bed. He was *holding his hands* behind his back and appeared to be trying to free them from some imaginary constriction. After carrying on in this way for about an hour, he got up, and, with his hands still in the same position, crept stealthily into the hospital grounds. According to orders I had given for the safety of the staff, he was not followed. After twenty minutes he returned in a state of more or less normal consciousness. As he was being put to bed the nurse noticed deep weals like rope marks on each arm, the patient being apparently unaware of their presence. Next day the marks were still visible and were observed by myself and others. The patient had only a vague recollection of what had happened the previous night. By the evening of April 11 the marks had disappeared, except for some residual subcutaneous hæmorrhagic staining.

On the night of April 11 the incident was abreacted under narcosis. At 11.10 P.M. I gave him 5 c.cm. of 'Evipan' intravenously. He slept for fifteen minutes. Then he talked in a meandering way, tossed about on the couch, got on to the floor, and started crawling round the room in a partially dissociated state. Suggestions directed to stimulate the dissociated experience were without effect (this lack of suggestibility was characteristic of him). Soon he returned to normal consciousness without any change in the appearance of his forearms having been observed. He remarked to me that he had "nearly got there"—i.e., reached the dissociated experience—but had then "come awake again."

At 12.15 A.M. I gave him another 3 c.cm. of evipan. He slept for a few minutes and then began reciting poetry. (This was a common prelude to his somnambulism.) Ten minutes later he began to toss and turn on the couch, with his hands behind his back. As he appeared to be *in* a completely dissociated state, I turned the light full on him. I watched him writhing violently for at least three-quarters of an hour. After a few minutes weals appeared on both forearms; gradually these became indented; and finally some fresh petechial hæmorrhages appeared along their course.

Then he got up and crept stealthily through the door into the hospital grounds. I followed him. When he began running, still with his hands behind his back, I lost trace of him in the dark for about ten minutes. When I found him again he was in a partially dissociated state, from which he regained normal consciousness about ten minutes later. He then gave a clear account of everything that had happened and related the incident to his experiences in hospital in India.



Photograph of patient's right forearm with indentations resembling rope marks, which appeared during abreaction under narcosis.

Next morning the marks were still clearly visible and were photographed (see figure).

Possibility of Trickery.—The first time the marks were observed trickery cannot be ruled out; the patient could have tied a piece of rope round his forearms while he was alone in the garden and discarded it on returning to the ward. On the second occasion, however, strict observation during the reappearance of the marks made trickery impossible; so it is difficult to see how the occurrence can be explained in any way other than as a genuine psychosomatic phenomenon. Moreover, for any such trickery there must be a motive, and neither I nor my colleagues could detect any possible motive, conscious or unconscious, for such behaviour. He was a man of excellent character in all respects. In the course of a long and arduous treatment I came to know him well and I have since maintained a social contact.

OTHER CASES

This type of localised somatic manifestation is not so unusual as is generally supposed.

During the abreaction of a man who had been concussed and buried by a fly-bomb a year previously, I found on the left ankle, on which a beam had fallen in the original incident, a swelling which increased the circumference of the ankle by $^1/_2$ in.; and over the left orbit, where he had been struck on the same occasion, an ovoid swelling which increased the circumference of his head by $^1/_4$ in.; at both points he had acute pain for several hours afterwards.

During the abreaction of a merchant seaman, who had been immersed in very cold water for a long time, there appeared (besides much generalised autonomic disturbance) localised ischæmia of the extremities.

In a woman, aged 35, the abreaction of a riding accident, which had happened at the age of 10 years, was followed by petechial hæmorrhages and bruising along the line of the tenth rib on the right side, the side on which she was said to have fractured some ribs. This abreaction was also followed characteristically by several hours of acute pain at the site of the original injury.

I could add to the list from my own limited experience, and no doubt others could add much more. I have heard of striking instances from colleagues, but relatively few cases seem to have been published. It is well known that somatisations of this nature, though not often so dramatically convincing, are fairly common in the course of psycho-analytical treatment.

DISCUSSION

These phenomena show that when an experience, in which there has been somatic as well as acute psychical trauma, is dissociated from normal consciousness, the complex resulting from it may retain the living image, as it were, of the somatic and the psychical experience; and that, when such a complex is discharged into consciousness—even after remaining in a latent (unconscious) state for many years—the somatic component of the original experience may be re-expressed in somatic terms.

The mechanism through which this is effected is obscure, and its final elucidation must remain in the sphere of the neurophysiologist rather than the clinician. But the existence of some such mechanism has been proved beyond doubt by reliable clinical observations and carefully controlled experiments. Unfortunately the best publications relating to this work are nearly all in German, most of them untranslated, with the result that in this country there still exists much scepticism about matters in which perfectly sound scientific proof is not lacking. Skin-blisters, for instance, have been produced hypnotically at *specified points* on the body surface, with the exclusion of all possible sources of error. Localised urticaria of *specified areas* of the body has been produced by similar means; so also have œdema and cutaneous gangrene. Many cases of spontaneous hæmorrhage of a psychogenic nature have been described, and the phenomenon has been subjected to exact scientific demonstration by Schindler (1927), who reviewed the whole subject. The question of religious stigmata has been critically reviewed by Jacobi (1923). One can conclude that neural pathways undoubtedly exist by which psychic contents may be projected on to the body *in a highly specific manner*; and it is reasonable to suppose that, in such cases, the psychic content or image, with its emotional charge, acts as the afferent side of a reflex arc the efferent counterpart of which is supplied by the autonomic nervous system.

Somatisation during abreaction differs from the above-mentioned phenomena in that the emotionally charged image or complex is derived from a previous experience which was in itself psychosomatic; the link between psyche and soma is therefore already in existence. So it is not surprising to find that somatisation during abreaction is relatively common and may occur independently of a well-marked constitutional predisposition.

This finding is of general significance in that such traumatic experiences are not restricted to adult life or to the battlefield. They may occur also in the formative years of early childhood and may involve regions of the body other than the skin and subcutaneous tissues. Though the complexes resulting therefrom may differ in certain important respects from those described in the present case, there is no reason to suppose that there is any material difference in the principles of psychosomatic relationship to which they are subject.

CONCLUSION

These phenomena observed during abreaction demonstrate the particularly intimate association between mind and body in traumatic experiences which have not been accepted by and integrated with consciousness. They also indicate the important part played by the emotional charge, both in maintaining this psychic dissociation and in causing generalised or even highly specific bodily changes.

I wish to thank Dr. Noel Harris, physician in charge, Woodside Hospital, for permission to publish this article.

FURTHER OBSERVATIONS ON A VITAMIN-C SURVEY OF MEDICAL STUDENTS

M. Peter Durham
M.A., M.B. Camb.

Gordon E. Francis
Ph.D. Lond.

Arthur Wormall
D.Sc. Leeds

From the Departments of Anatomy and Biochemistry, St. Bartholomew's Hospital Medical College

Earlier reports have been made (Harrison, Mourant, and Wormall 1939, Francis and Wormall 1942) on vitamin-C surveys by saturation tests on the students of St. Bartholomew's Hospital Medical College. The results showed that, whereas the state of "saturation" of these subjects with regard to vitamin C was not significantly different in 1940 from that in 1939, there was a distinctly higher degree of "unsaturation" in 1941. Although the results in 1941 did not suggest that most of the subjects were very seriously deficient in vitamin C, the difference between the 1940 and 1941 results was sufficient to justify a continuation of the survey to determine whether a prolonged shortage of certain fresh fruits during the war would lead to any further increase in the degree of unsaturation of the subjects of our tests. Further observations were therefore made in 1943 and 1944, and the opportunity was taken to study some other aspects of saturation with vitamin C.

The main objects of the investigations described in this paper were (1) to compare the results of the saturation tests in 1943 and 1944 with those of 1939–41; (2) to determine how long any body "reserve" of the vitamin which might be built up by saturation would remain effective, so far as these saturation tests are concerned; (3) to emphasise the seasonal differences and the greater degree of unsaturation in spring compared with other seasons; and (4) to attempt to correlate the results of the saturation tests with observations on follicular hyperkeratosis among the subjects.

Four groups (A, B, C, and D), each originally of 35 students, were selected for these tests, and it was decided to carry out saturation tests on them according to the following scheme:

	GROUPS TESTED			
November, 1943 ..	A	B	—	—
February, 1944 ..	A	—	C	—
May, 1944	A	B	C	D

A slight modification of this scheme was, however, made later, for the results of the tests in February, 1944, indicated that there would be very little point in testing group B in May, 1944. As group A did not appear to "benefit" in February from saturation three months earlier, it seemed highly improbable that group B, saturated like group A in November, 1943, would show any benefit six months after saturation.

EXPERIMENTAL

Subjects.—The subjects, some of whom took part in the 1941 tests, were all students of our medical college. Approximately a third of them had practically all their meals in college in Cambridge during term-time, one or two lived at home, and the rest in lodgings. During the vacations practically all lived at home. They were asked not to take any preparation containing synthetic ascorbic acid during these investigations, but at a later date it was found that a few of the subjects had taken preparations of this type. The results with these individuals, and those on a few subjects who left Cambridge before the completion of their tests, are not included in this report. This explains the differences in the numbers of subjects in the four groups, but as the minimum in the important groups in the final tables is 31, it may be claimed that the results are of statistical value.

Saturation Tests.—These were made by the method of Harris and Abbasy (1937), and full details are given in our earlier publication (Francis and Wormall 1942). The amount of ascorbic acid excreted during a two-hour afternoon period following a dose of 5 mg. of the vitamin (B.D.H.) per lb. of body-weight at 9 A.M. or 10 A.M. was determined, and the subject was considered saturated when he excreted in the two-hour period at least 5 mg. per 14 lb. of body-weight. This is essentially the criterion proposed by Harris and Abbasy, except that their afternoon urine-collection period was two and a quarter hours; these authors also suggested that the number of test doses required beyond the second might be taken as an index of the relative deficiency of the past intake of vitamin C by the individual.

Hair-follicle Tests.—Since it is difficult to measure precisely the extent of hyperkeratosis in any one subject, it was thought desirable that these tests and the chemical tests should be carried out as almost entirely separate investigations. Thus M. P. D., who made the hair-follicle tests, was completely unaware, when he made these tests, of the results of the chemical tests. No comparison of the results was made until the two series were completed, and in this way, it is hoped, a completely unbiased set of results was obtained. Where possible the hair-follicle tests on any one subject were made at about the same time as the start of the saturation tests. In the February series, however, some of the former tests were made rather later (1–4 weeks) than the chemical tests, but from the observations made in this work, and from those of other investigators, it does not seem likely that any significant change in the hyperkeratosis is likely to have taken place during this interval.

Dr. George Graham, at whose suggestion these hair-follicle tests were made, suggested that it would be advisable for the subjects with hyperkeratosis in February and March to receive suitable ointment treatment in readiness for the May observations, but we were not able to adopt this suggestion owing to examinations and the Easter vacation. The possibility that the hyperkeratosis might persist three months after saturation with vitamin C and affect the results of the tests in May is discussed later in this paper.

The back of the thigh has been reported to be the first region of the body to show hyperkeratosis. This site was therefore chosen for an estimate to be made of the degree of hyperkeratosis in each subject. A piece of cardboard with a 2-in. square cut out of it was placed over the back of the thigh just below the fold of the buttock, and the number of diseased hair follicles in the square was counted. If none was visible the whole of the back of the thigh was examined to see whether "occasional" ones were present, and to make sure that the state of the hair follicles in the chosen area was typical. The results were recorded as follows:

+ + + = 13–20 diseased follicles per 2-in. square
+ + = 7–12 " " " " "
+ = 1–6 " " " " "
± = An occasional diseased follicle seen on the leg
— = None
Abs. = Absent or not available for the test

DISCUSSION

The results of the saturation tests and the hyperkeratosis tests for the individual subjects of the various groups are given in tables I, II, and III, with a summary of the saturation-test results in table IV. No tests were made on group B after November, 1943, for reasons given above, and details of the individual results with this group are therefore omitted, but the group results are included in table IV.

In a previous communication (Francis and Wormall 1942) it was shown that a distinct increase in "unsaturation" with regard to vitamin C occurred among our students from July, 1940, to July, 1941, presumably owing to the decreased supplies of oranges and certain other fresh fruits. For this and similar comparisons observations were made where possible at about the same part of each year, for there is a marked seasonal variation in our state of saturation with vitamin C. The results presented in the present paper suggest that the subjects investigated in the latter part of 1943 and the first half of 1944 were not more "unsaturated" than were similar subjects in June and July, 1941. Several of the subjects showed, however, a high degree of unsaturation in 1943 and 1944, requiring 5, 6, or (in one case) 7 large test doses—i.e., 3·5–5 g. of the vitamin—before they were saturated, and these high requirements approach those recorded in the literature for cases of scurvy. Without entering on the vexed question of the relationship between the occurrence of scurvy or subclinical scurvy and a higher degree of unsaturation as assessed by saturation tests it may be noted that some authors—e.g., Paterson and Daynes (1941)—have reported an increase in the incidence of scurvy in this country during the war. Our own surveys have certainly indicated a definite increase in the number of relatively unsaturated individuals during this period.

In these investigations it has been noted that there is a tendency for an individual who is relatively unsaturated in one set of tests to be relatively unsaturated again at

subsequent tests. This might well be expected where the interval between the tests is long, but it seems rather surprising when the interval is only three months. Thus relatively unsaturated subjects of group A who received sufficient ascorbic acid to saturate them in November, 1943, were three months later again relatively unsaturated compared with other members of their group or even compared with individuals who had not received the test doses in November; three months after the second saturation they were again more unsaturated than the others. In group C also, the more unsaturated subjects in February tended to be more unsaturated than the other members of their group three months later. Several reasons might be advanced to explain the tendency of these unsaturated subjects to become unsaturated again very quickly. These individuals might (1) regularly select, by choice or for some other reason, a diet relatively deficient in vitamin C; (2) show a high rate of utilisation or destruction of the vitamin in the tissues; (3) excrete abnormally large amounts in the urine owing to a relatively low renal threshold for ascorbic acid; or (4) show some deficiency in the absorption of the vitamin from the alimentary tract. Of these and other possible explanations the first two appear to be the most feasible, and in the case of a few of our subjects we have satisfied ourselves that the first is probably the factor concerned.

Vitamin C, unlike some of the other vitamins—e.g., A, D, and E—is not stored in the ordinary sense in the animal body, but there is undoubtedly, in the tissues of a saturated individual, a "reserve" which might be regarded as a useful "balance" against a future emergency. This need not imply, of course, that saturation with this vitamin is desirable or at all necessary for the proper functioning of the metabolic processes of the body. It is not our intention to discuss at length this question of saturation and the value of the saturation tests as designed by Harris and his colleagues (Harris and Abbasy 1937, Harris 1942); in our experience, however, these tests, because of their simplicity and the clear-cut results, appear to be eminently satisfactory for the purpose for which they were intended. Perhaps it is sufficient to quote Harris (1943): "The purpose of the saturation test is to say whether the intake has been above or below some accepted standard of intake, and if below how much below. Whether saturation is desirable or not is beside the point."

Opinions are divided on the question of the "reserve" value of the vitamin C in the tissues. Zilva (1941) considers that the body ascorbic acid of a saturated animal does not act in any well-marked degree as a reserve, and he does not consider that the body can store this vitamin (cf. also Zilva 1936). Other authorities believe, however, that the reserve may have a real value; and, although it is not our wish to enter this discussion, we decided that it would be of interest in our survey to determine how long any reserve acquired during the saturation tests would remain effective, as judged by later saturation tests.

Information on this point is rather scanty, although Harris (1943), from observations over a period of years, has reached the conclusion that an interval of six months or more between successive saturation tests is sufficient to ensure that the effect of previous saturation in building up the "reserves" has worn off. Atkins (1943) found a difference of only three-quarters of a dose in the saturation-test requirements of two groups, one of which had been saturated four months previously.

The results of our investigations, summarised in table IV, show that the individuals (group A) saturated in November, 1943, were only slightly less unsaturated (0·23 of a test dose on an average) in February, 1944, than were other members of our student population—i.e., they had almost entirely lost in three months any "advantage" from the saturation. The tests made in May showed, however, that those saturated three months previously (groups A and C) were definitely less unsaturated (0·59 of a test dose) than were other individuals (group D). This difference between the results for the two three-month periods can perhaps be explained by the difference between the changes in the state of vitamin-C nutrition of the population, due primarily to seasonal variations in the dietary supply of the vitamin. The period covering these tests was one when we might reasonably expect, from our own earlier observations and from those of other investigators, a distinct increase in the number of doses required to give saturation over the period November to February, with a much smaller increase from February to May. The fact that the latter increase did not arise we attribute largely to the fact that there were a few issues of oranges during the spring of 1944.

The conclusions which might tentatively be reached from the results summarised in table IV are that any *extra* "tissue reserve" of vitamin C resulting from saturating doses will normally be largely lost by the body in the course of three months or less, if the dietary intake of the vitamin over this period is insufficient to meet the body requirements. Where the dietary intake is adequate there may be retention of part of the "reserve" for over three months. Perhaps it is only to be expected that the extra reserve should be dissipated in a "slump" period—i.e., that the more saturated individuals should use or lose vitamin C at a greater rate than those who are less saturated—but it was rather surprising to find that

TABLE V—COMPARISON OF SATURATION TESTS AND HYPERKERATOSIS TESTS IN GROUPS A AND C

his extra loss was so high. Two groups of subjects, ne in a "saturated" condition and the other with an pparent "deficiency" of about 1200 mg. of ascorbic cid per subject in November, 1943, had both acquired ractically the same degree of unsaturation three months ater, after living on similar diets and under similar onditions. Over this period the previously saturated ndividual had thus used or lost, on an average, 12–15 mg. f ascorbic acid a day (almost half the daily requirement n the League of Nations standard) more than the indi-idual who was not previously saturated. This observa-ion is consistent with the view that the body economy is nore wasteful of its vitamins when they are in good supply.

This question of a reserve produced by large doses of he vitamin is naturally one of practical importance. lthough it is usually possible and more economical to ive protection against scurvy by supplementing a eficient diet with small daily doses of the vitamin, it vould undoubtedly be of interest to know how far these laily doses can be replaced by larger and less frequent nes. Information on this point will be difficult to btain, but Zilva (1941), in a comparison of the data or man and guineapigs, has tentatively suggested that doses of the order of 100 mg. of ascorbic acid, given at intervals of days or even weeks, may effect at least minimal protection against scurvy.

TABLE VI—COMPARISON OF SATURATION TESTS AND HYPERKERATOSIS TESTS IN GROUP D

Hyper-keratosis reading	No. of subjects	May, 1944							Aver. no. of doses per subject
		Saturation tests							
		Doses required							
		1	2	3	4	5	6	7	
–	10	0	5	0	2	1	1	1	3·6
±	3	0	2	0	1	0	0	0	2·7
+	15	2	4	4	4	0	1	0	2·9
++	1	0	0	0	1	0	0	0	4·0
+++	3	0	2	0	0	0	1	0	3·3

The development of follicular hyperkeratosis in individuals with scurvy has been noted by many authors (Nicolau 1918, Wiltshire 1919, Scheer and Keil 1934, Prunty and Vass 1943). Further, Crandon et al. (1940) found that the hyperkeratotic papules appearing in subjects on a diet deficient in vitamin C but not in the other known factors disappeared after the injection of this vitamin. There is, however, evidence that hyperkeratosis may be associated with vitamin-A and other deficiencies. Lowenthal (1933) reports the association of follicular papules with night blindness and xerophthalmia, all of which were cured together by the administration of vitamin A. Scheer and Keil (1934) state that the types of follicular lesions associated with hypovitaminosis A and with scurvy are indistinguishable in their earlier stages, but differentiation can be made at later stages. Frazier and Hu (1936) do not support this view, however, and they conclude that the cases associated with scurvy are due to diets generally deficient in vitamins, particularly vitamin A (cf. also Frazier et al. 1943).

A comparison of the results of our skin-tests with those of the saturation tests for the same subjects (tables I, II, and III) does not show any definite correlation between hyperkeratosis and a deficiency of vitamin C. Thus quite often a subject who required 5, 6, or 7 large doses of the vitamin before he was saturated showed no sign of hyperkeratosis, and conversely some with well-marked hyperkeratosis became saturated at the second or even the first dose of the vitamin. A comparison of the saturation-test requirements of those subjects showing different degrees of hyperkeratosis (cf. tables V, VI, and VII) also gives no indication of a close relationship between "unsaturation" with vitamin C and hyperkeratosis; thus the number of test doses required by subjects showing well-marked hyperkeratosis (++ or +++) usually differed little from the requirement of those showing no hyperkeratosis. Another method of analysis which has been used involves the division of the subjects into two arbitrary groups, "relatively saturated" and "relatively unsaturated," according to the number of test doses required. If those requiring three or more doses of the vitamin are classified as "unsaturated" and the others as "saturated," it is found that the number of subjects showing +, ++, or +++ in the hyperkeratosis tests is 37% for the "saturated" subjects and 35% for the "unsaturated." If the criterion for "unsaturation" is four or more test doses, the figures are 37% and 34% respectively, and 37% and 25% respectively if "unsaturated" is regarded as a requirement of five or more test doses. The differences between the figures for the two groups are certainly within the limits of experimental error, except in the case of the last comparison, where the small number of subjects in the "unsaturated" group renders the result less reliable, and it will be noted that in every case there was slightly more hyperkeratosis among the relatively saturated individuals.

TABLE VII—SUMMARY OF TABLES V AND VI

Hyper-keratosis reading	No. of subjects	Saturation tests							Aver. no. of doses per subject
		Doses required							
		1	2	3	4	5	6	7	
–	73	2	30	15	18	5	2	1	3·1
±	28	6	6	9	6	1	0	0	2·6
+	40	3	16	11	9	0	1	0	2·8
++	9	1	3	1	3	0	1	0	3·1
+++	8	1	2	2	2	0	1	0	3·1

Similar conclusions are reached when the figures for the individual groups are analysed separately, and the results for group D in May, a group of subjects not previously given saturating doses, were similar in this respect to those for groups A and C; this appears to overrule any objection to the results of the hyperkeratosis tests on groups A and C in May on the ground that the interval of three months between the two series of tests was not sufficient to allow the earlier hyperkeratosis to disappear.

It is not suggested that the results of this preliminary investigation rule out all possibility of a relationship between follicular hyperkeratosis and a deficiency of vitamin C, though in our subjects there were undoubtedly many cases of hyperkeratosis in individuals who, judged by saturation tests, were not at all "unsaturated" with regard to vitamin C. It is hoped that at some future date it will be possible to study this problem more fully, with a frequent examination of the subjects after saturation to determine in which cases the hyperkeratosis disappears after the saturation process.

SUMMARY

Vitamin-C saturation tests have been carried out on groups of medical students (31 34 in each group) in November, 1943, and February and May, 1944, to determine whether or not there is retention, at the end of three months, of any "body-reserve" of the vitamin resulting from the saturation tests.

An attempt has also been made to find out whether there is any relationship between "unsaturation" with subsequent tests. This might well be expected where the interval between the tests is long, but it seems rather surprising when the interval is only three months. Thus relatively unsaturated subjects of group A who received sufficient ascorbic acid to saturate them in November, *1943, were three months later again relatively unsaturated* compared with other members of their group or even compared with individuals who had not received the test doses in November; three months after the second saturation they were again more unsaturated than the others. In group C also, the more unsaturated subjects in February tended to be more unsaturated than the other members of their group three months later. Several reasons might be advanced to explain the tendency of these unsaturated subjects to become unsaturated again very quickly. These individuals might (1) regularly select, by choice or for some other reason, a diet relatively deficient in vitamin C; (2) show a high rate of utilisation or destruction of the vitamin in the tissues; (3) excrete abnormally large amounts in the urine owing to a relatively low renal threshold for ascorbic acid; or (4) show some deficiency in the absorption of the vitamin from the alimentary tract. Of these and other possible explanations the first two appear to be the most feasible, and in the case of a few of our subjects we have satisfied ourselves that the first is probably the factor concerned.

TABLE IV—SUMMARY OF SATURATION RESULTS

Vitamin C, unlike some of the other vitamins—e.g., A, D, and E—is not stored in the ordinary sense in the animal body, but there is undoubtedly, in the tissues of a saturated individual, a "reserve" which might be regarded as a useful "balance" against a future emergency. This need not imply, of course, that saturation with this vitamin is desirable or at all necessary for the proper functioning of the metabolic processes of the body. It is not our intention to discuss at length this question of saturation and the value of the saturation tests as designed by Harris and his colleagues (Harris and Abbasy 1937, Harris 1942); in our experience, however, these tests, because of their simplicity and the clear-cut results, appear to be eminently satisfactory for the purpose for which they were intended. Perhaps it is sufficient to quote Harris (1943): "The purpose of the saturation test is to say whether the intake has been above or below some accepted standard of intake, and if below how much below. Whether saturation is desirable or not is beside the point."

Opinions are divided on the question of the "reserve" value of the vitamin C in the tissues. Zilva (1941) considers that the body ascorbic acid of a saturated animal does not act in any well-marked degree as a reserve, and he does not consider that the body can store this vitamin (cf. also Zilva 1936). Other authorities believe, however, that the reserve may have a real value; and, although it is not our wish to enter this discussion, we decided that it would be of interest in our survey to *determine* how long any reserve acquired during the saturation tests would remain effective, as judged by later saturation tests.

Information on this point is rather scanty, although Harris (1943), from observations over a period of years, has reached the conclusion that an interval of *six months or more between successive saturation tests is sufficient* to ensure that the effect of previous saturation in building up the "reserves" has worn off. Atkins (1943) found a difference of only three-quarters of a dose in the saturation-test requirements of two groups, one of which had been saturated four months previously.

The results of our investigations, summarised in table IV, show that the individuals (group A) saturated in November, 1943, were only slightly less unsaturated (0·23 of a test dose on an average) in February, 1944, than were other members of our student population—i.e., they had almost entirely lost in three months any "advantage" from the saturation. The tests made in May showed, however, that those saturated three months previously (groups A and C) were definitely less unsaturated (0 59 of a test dose) than were other individuals (group D). This difference between the results for the two three-month periods can perhaps be explained by the difference between the changes in the state of vitamin-C nutrition of the population, due primarily to seasonal variations in the dietary supply of the vitamin. The period covering these tests was one when we might reasonably expect, from our own earlier observations and from those of other investigators, a distinct increase in the number of doses required to give saturation over the period November to February, with a much smaller increase from February to May. The fact that the latter increase did not arise we attribute largely to the fact that there were a few issues of oranges during the spring of 1944.

The conclusions which might tentatively be reached from the results summarised in table IV are that any *extra* "tissue reserve" of vitamin C resulting from saturating doses will normally be largely lost by the body in the course of three months or less, if the dietary intake of the vitamin over this period is insufficient to meet the body requirements. Where the dietary intake is adequate there may be retention of part of the "reserve" for over three months. Perhaps it is only to be expected that the extra reserve should be dissipated in a "slump" period—i.e., that the more saturated individuals should use or lose vitamin C at a greater rate than those who are less saturated—but it was rather surprising to find that

	+++	1	0	0	1	0	0	0	3·0	+++	2	1	0	0	1	0	2 5

phantasies in this period became non-sexual, in contrast to those of the early part of his service in the M.E., and they were largely concerned with his future. Frank sexual dreams had become rare, and nocturnal emissions, previously frequent, excessively rare. He recollected none in the preceding six months.

He returned to the U.K. in January, 1945, when he married. His attitude towards the marriage, both before and after, was difficult to assess. He insisted, rather too vehemently, that his feelings for his wife had not changed, and an impression of "duty" was conveyed. During the first six days following marriage menstruation prevented coitus, but in the remaining 21 days before his return to the M.E. he had intercourse once. This apparently was achieved satisfactorily. There was no active distaste, but his response was rather apathetic. There was no further desire on his part. He presented no evidence of homosexual trends.

Examination.—He was peculiarly and attractively diffident in manner and contrived successfully to appear tidy in hospital "blues." Weight 80 kg. Complexion high, skin of fine texture. Comparison with previous photographs showed no change in the facies. The beard was a moderate normal growth. The hair on the chest was very scanty and restricted o mid-sternum. The distribution of pubic hair tended to he transverse feminine; dense over pubis and scanty towards he umbilicus. He was well nourished but not adipose. The at distribution was consistent with that of the normal male, ut there was the suggestion of increased deposition round he pelvic girdle, notably suprapubically.

The breasts were well developed. The nipples were rather prominent, with readily stimulated erectile tissue. There was no increased pigmentation either of nipples or areolæ. Montgomery's tubercles were well marked. On palpation he breasts had the consistence of those with chronic mastitis No secretion was expressed. (Fig. 1 shows the bodily configuration.)

The penis and testes were of a large normal size There was no evidence of atrophy of prepuce or glans. A minor bilateral dilatation of the spermatic venous plexus was present, The prostate, per rectum, was not enlarged.

A tumour was felt in the left subcostal area, occupying the left hypochondrium and lumbar area as far medially as the mid-Poupart line. (The mass had been mistaken for an enlarged spleen with more than a little justification.) It could be defined as a prolongation from above, lying behind gut and descending on inspiration. The lower pole was four finger-breadths below the tip of the ninth rib and towards this pole there was apparent regular enlargement

Blood-pressure was 120/80.

Examination of the remaining systems demonstrated no abnormality.

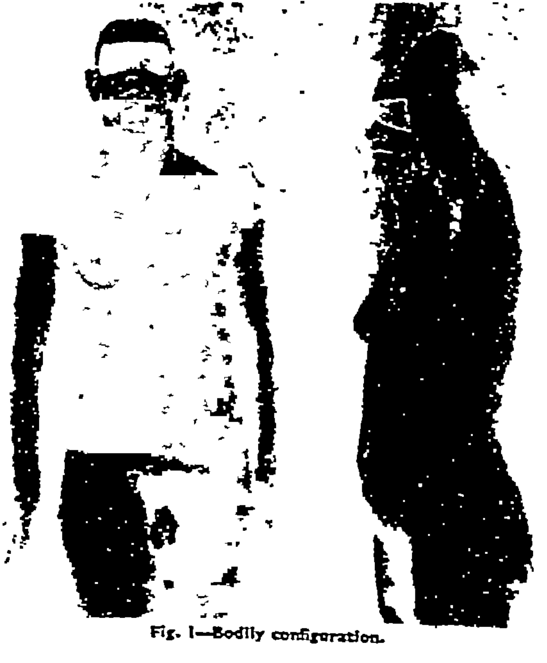

Fig. 1—Bodily configuration.

Investigations.—The radiological reports quoted below were made by Major W. G. Scott-Harden.

(1) "*Straight Plate*: the left kidney is displaced downwards by a large soft-tissue tumour; the tumour had not displaced the splenic flexure and does not fill the peripheral part of the left upper abdomen."

(2) "*Excretion Urography*: the upper calices and part of the renal pelvis are almost completely obliterated, with sharp delineation and no erosion" (fig. 2).

"*Opinion*: the appearances are consistent with a large left suprarenal tumour; infiltration of the upper pole of the left kidney cannot be excluded, although the urographic picture is quite in keeping with external pressure effects only"

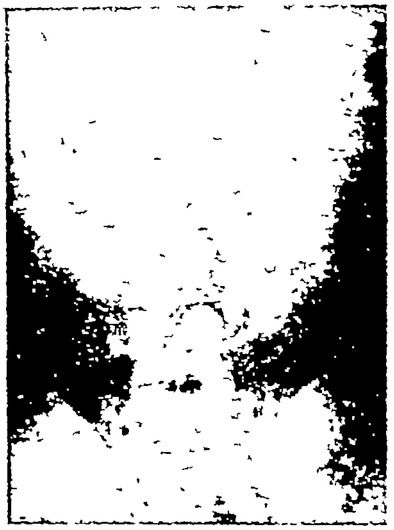

Fig. 2—Radiogram showing downward displacement of left kidney and obliteration of its upper calices and a part of its pelvis.

(3) "*Chest*: lung fields clear."

Other investigations gave the following results:—

Blood-cholesterol (April 1)	154 mg./100 c.cm.
Blood-urea (April 1)	20 mg./100 c.cm.
Friedman's test (April 1)	Positive.

(Neither a quantitative Friedman nor assay of œstrogen could be carried out.)

Glucose tolerance (May 10):

Fasting: 100 mg./100 c.cm.	½ hour: 137 mg./100 c.cm.
1 hour: 117 mg./100 c.cm.	1½ hours: 117 mg./100 c.cm.
2 hours: 110 mg./100 c.cm.	

Blood-count (April 10): Hb 103% (Sahli corrected), erythrocytes 5,290,000/c.mm., leucocytes 8200/c.mm. (polymorphs 68%, eosinophils 1%, mononuclears 4%, lymphocytes 27%).

Erythrocyte-sedimentation rate (Westergren): April 17, 30 mm./1 hour; April 19, 26 mm./1 hour; April 22, 28 mm./1 hour.

Urinary chloride concentration (April 15) on modified Cutler diet was within normal limits.

Semen: volume and motility normal

Urine normal on repeated analyses.

Operation.—On April 24, under nitrous oxide, oxygen, and ether anæsthesia, after 'Pentothal' induction (Major Gordon Neil), Lieut.-Colonel V. W. Dix excised the tumour through the left lumbar incision with subperiosteal resection of the last rib. No difficulty was encountered in separation of the tumour from the kidney. At the beginning of the operation intravenous saline drip was started.

Postoperative Course.—Recovery from operation was completely uneventful. The drip was discontinued at the end of 36 hours after a total of five pints. On May 14 (twenty days after the operation) Friedman's test was negative.

On June 6 (forty-three days after the operation), before evacuation to U.K. for deep radiotherapy, he was re-examined. He stated that his beard was of stronger growth, and at night he felt tempted to shave again. Interest in the opposite sex had revived, and erections had become frequent. (The first was on the eleventh day after operation.) He had three sexual dreams associated with emission, the first of them on the seventeenth day after operation. He referred, in a few terse phrases, to the lost opportunities of his honeymoon.

Examination.—He had the same rather diffident attractive manner noted at the original examination. No changes in the breasts were noted, save that there was a fairly profuse growth of downy periareolar hair. Erythrocyte-sedimentation rate 10 mm. Friedman's test negative.

Pathology.—Macroscopically the specimen was a large multilobulate tumour, consisting mainly of one large lobe and three secondary, one of which had been detached to facilitate removal at operation. It weighed 1420 g. and measured 21 cm. from upper to lower pole, or 23 cm. with secondary lobe in position; transverse diameter 15 cm.; anteroposterior diameter 10.5 cm.

the vitamin, as measured by the number of large test doses required to produce saturation, and the occurrence of hyperkeratosis in these subjects.

Subjects saturated in November, 1943, required three months later almost the same number of test doses to give saturation as did other subjects who had not previously received these large doses of ascorbic acid.

In May, 1944, the subjects who had not been tested before required, on an average, 0·6 of a test dose more than did those who had been saturated three months previously.

These observations suggest that an individual saturated with ascorbic acid will not necessarily show three months later any advantage, so far as these saturation tests are concerned, over an individual who has not previously been saturated. Some advantage—i.e., retention of part of the "body-reserve"—may be shown where the intervening period involves little or no increase in the degree of unsaturation of the population.

Subjects who were relatively unsaturated in the November tests tended to be relatively more unsaturated again in the February and also in the May tests. Several possible explanations of this are discussed.

The average number of test doses required to effect saturation was 1·8 in November, 1943; 3·1 in February, 1944; and 3·1 in May, 1944. These values do not compare unfavourably with the value of 3·25 for June and July, 1941, but they were appreciably higher than the figures obtained in 1939 and 1940 (about 1·5).

No significant correlation was observed between the occurrence of hyperkeratosis in these subjects and the degree of "unsaturation" with ascorbic acid.

We are grateful to Dr. George Graham for his suggestions and advice in connexion with the hair-follicle tests and for his interest in this vitamin survey. We also want to thank Mr. L. J. Hudson for his technical assistance in the chemical tests, and Messrs. British Drug Houses Ltd. for a supply of ascorbic acid.

"... Defining active anti-Nazis as those who opposed the régime through evidence of overt acts, and passive anti-Nazis as those who suffered through refusal to make concessions as proven by concrete events; and defining Nazis as members of the party, whether active or passive, enthusiasts or merely nominal members, significant psychological differences are discernible. . . . As compared with the others, studies of anti-Nazis revealed fewer instances of harsh, disciplinary fathers, more instances of mothers who openly demonstrated affection. Anti-Nazis were more frequently "only" children or favourite children. They had more frequently parents of different religions and different nationality. They had more frequent experience of travel (six months or longer) in foreign countries, which influenced their political or social viewpoints, and more frequently intimate friendships with people who were anti-militaristic or anti-Nazi. . . . The family background of anti-Nazis gave evidence, on the basis of points already enumerated, of more affection, less domination, more expression, higher self-esteem. They were more likely, for that reason alone, to differ from their uncritically compliant German fellow-men, trained so thoroughly in acceptance of authority and discipline."—Dr. D. M. LEVY, speaking to the New York Academy of Medicine on Nov. 20.

FEMINISATION ASSOCIATED WITH CARCINOMA OF THE ADRENAL CORTEX

A. J. S. McFADZEAN
M.B. Glasg.
MAJOR R.A.M.C.; MEDICAL SPECIALIST

FROM the suprarenal cortex Reichstein (1936) isolated adrenosterone, which has androgenic properties. Cortilactin, capable of producing hypertrophy of the mammæ and lactation, was isolated by Brownell et al. (1935), and Callow and Parkes (1936) obtained extracts with œstrone-like and progesterone-like activity.

There is remarkably complete clinical evidence of pathological conditions of the suprarenal cortex directly or indirectly responsible for excess secretion of androgen or œstrogen. This is especially true of androgen. Such pathological conditions may be a cortical hyperfunction, with or without hyperplasia, or a cortical adenoma (a somewhat rare cause), or a carcinoma of the cortex.

Cortical carcinoma associated with excess secretion of androgen is relatively common. In the male there is no gross sexual change save in the prepubertal period, when isosexual precocity develops. In the female virilism is the result.

Carcinoma associated with excess of œstrogen in the female before puberty produces isosexual precocity. Such tumours in the male occasion feminisation and are very rare. The first case in the literature was reported by Bittorf (1919). Since then 5 further cases have been recorded: 1 by zum Busch (1927) which was alluded to by Parkes Weber (1926), 2 by Holl (1930), 1 by Lisser (1936), and 1 by Simpson and Joll (1938). The present case constitutes the seventh.

The second case described by Holl (1930) and that described by Simpson and Joll (1938) are of special importance. Holl's is the only recorded case in which the tumour was successfully excised, with subsequent complete regression of symptoms. The importance of Simpson and Joll's case is due to the biological assays of œstrogen excretion in the urine. After excision of the primary growth œstrogen in excess was not demonstrable in the urine, and this was associated with clinical improvement. With the appearance of secondary growths and coincident recrudescence of symptoms œstrogen was present in excess.

CASE-RECORD

A lance-corporal, aged 29, was admitted to a Middle Eas general hospital on March 23, 1945, with a history of 18 hours intermittent shivering, headache, and general malaise. Nex day he was apyrexial and well. He was seen in consultatio with the M.O. i/c ward on the 26th, when the case wa presented as one of pyrexia of undetermined origin (resolved associated with gross splenomegaly.

He had served four years and three months in the Middle East and, apart from repeated periods in hospital with "dermatitis" since January, 1942, he had been well.

In October/November, 1943, he first noticed enlargement of the breasts. They rapidly increased in size in a couple of months or so, without causing any symptoms. During the six months before admission, though there was definite and progressive increase, it was slight. At no time had he abdominal discomfort, and, apart from skin lesions, he had been perfectly well. His appetite was normal throughout, and his ability to perform heavy physical tasks was unimpaired. There had been progressive increase in his weight in the past year.

He began shaving at the age of 15/16 and subsequently shaved daily. The hair on the chest was always scanty and no recent change had been observed. He believed that the distribution of pubic hair had altered, tending to be more sparse towards the umbilicus.

He had always been a normal male in outlook before the onset of breast enlargement. He had had intercourse at intervals since the age of 19 until leaving for the Middle East, where he had been continent. In the year before examination his interest in members of the opposite sex waned. His

After denervation of the left suprarenal and right hemi-adrenalectomy, without therapy to the pituitary, the Friedman became negative. The mechanism is obscure.

Lacassagne (1933) claimed inhibition of spermatogenesis in mice with exhibition of folliculin. In the present case the semen, on such examination as was carried out, was normal. Mathias (1922) reported good spermatogenic tissue on section of the testes in Bittorf's case. The prostate was not enlarged, nor was there dysuria, a finding also in Simpson and Joll's case. This is contrary to what one would expect from the experiments of Lacassagne (1933) in mice and of subsequent workers in other animals. This experimental action of œstrogen, however, has been shown to be inhibited by testosterone, and this may be the explanation in the present case—i.e., under influence of gonadotrophic hormone secretion of testicular androgen was maintained

The distribution of the pubic hair in Holl's first case was feminine, but onset was at or about puberty. In his second case, though the distribution was essentially masculine, hair on chest and abdomen became very sparse. The distribution in Lisser's case was unchanged. In the present case hair had always been scanty on the chest, and there was no change; but the hair on the abdomen became more sparse.

The weight increased in Bittorf's case; the increase was well marked in Holl's second case and initially in Simpson and Joll's case, the increase in twelve months from the onset being 28 lb.

Pain or any discomfort whatever was surprisingly absent in the present case in view of the size of the tumour and the multiple hæmorrhages It was prominent in two of the cases described: pain in the left flank was the cause of admission to hospital in Lisser's case; and left subscapular pain, approximately a year after the onset of breast enlargement, in Simpson and Joll's case compelled the patient to seek advice

Waning of the libido and subsequent impotence, with testicular atrophy, developed in Bittorf's case and in Holl's second case. In Bittorf's, impotence was complete seven months after the onset of breast enlargement. In that described by Simpson and Joll partial impotence was present approximately a year after onset. Holl's case was described as displaying no homosexual trends and completely disinterested in sex. Fifteen months from the start of breast enlargement the present case is known to have been potent. There was a gradual and progressive reduction in degree of heterosexuality, though he was still heterosexual before operation. How great that reduction was could be estimated after operation.

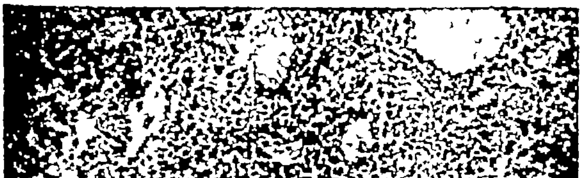

Fig. 4—Section of carcinoma of suprarenal cortex: above, low power; below, high power.

Greatly increased heterosexuality constituted the most striking change postoperatively. Return of interest in members of the opposite sex was rapid. Eleven days after operation there was an erection, and subsequently these became frequent. Seventeen days after, he had a frankly sexual dream with emission. Within the limited period of postoperative observation (forty-three days) no change in the breasts was noted. There was a distinct increase in beard growth and fairly profuse growth of downy areolar hair.

The postoperative course in Holl's second case was very striking. Before operation the patient was impotent and completely disinterested in sex. The penis and testes were small. The breasts were much enlarged, painful, and tender, with deeply pigmented and enlarged nipples. The facies were heavy and so changed that he was not recognised by his acquaintances. Seven days after operation the breasts were less painful and tender and, at the end of a month, erection and emission took place. Within a few months there was return of heterosexual desire, and sexual intercourse was resumed. Six months after the operation the penis and testes were of normal size, the breasts were small and not tender, and the nipples were consistent with those of a normal male.

If malignant change coincides with the start of breast enlargement, then the malignancy, clinically, of the tumour in the present case was low. Seventeen months after onset the tumour was still operable. Holl's second case, Bittorf's case, and Simpson and Joll's case must similarly have been of a low degree of malignancy; zum Busch's, Holl's first, and probably Lisser's cases pursued a rapidly fatal course with multiple secondaries.

SUMMARY

A case of carcinoma of the left suprarenal cortex with feminisation in the adult male is described. The clinical features of such cases are briefly discussed, as are certain variations in the present case from those previously recorded.

My thanks are due to Lieut.-Colonel V. W. Dix for a display of manual dexterity not readily forgotten; Lieut.-Colonel C. J. Gavey for many kindnesses; Colonel W. E. Harvey, R C.P. laboratory, Edinburgh, for his consideration and excellent photomicrographs; Dr. W. W. Adamson for his opinion on the section; and Major W. G Scott-Harden for the high quality of the clinical photographs.

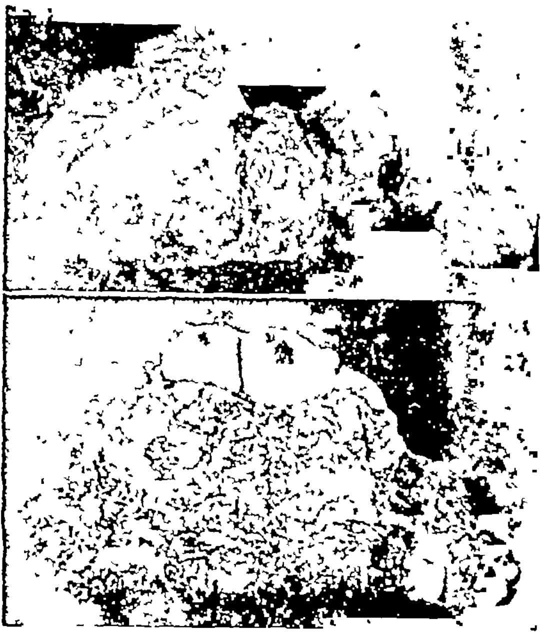

Fig. 3—Carcinoma of suprarenal cortex: above, as removed at operation and measuring 23 cm. in length; below, on section, showing multilobulate form, variegated appearance, and multiple hæmorrhages.

The tumour had a well-defined capsule, thinned over numerous small nodes. This was intact save at the upper posterior pole of the main lobe, where at two small areas the tumour had infiltrated through the capsule. Over the surface of the capsule coursed large tortuous thin-walled vessels (fig. 3).

On section the multilobulate form of the tumour was evident. Towards the centre of the main lobe was a "fibrous core" from which radiated well-marked trabeculæ. The cut surface had a variegated appearance. No normal suprarenal tissue could be identified. The greater part of the main lobe bore extraordinary similarity to the appearance classically associated with hypernephroma. The remainder of the tumour had a light-grey rather translucent colloid appearance. Multiple hæmorrhages had taken place (fig. 3).

Microscopically the appearances were those of an adenocarcinoma. The cells were arranged in groups or in columns. In parts there was resemblance in arrangement to the zones of the suprarenal cortex; notably the fasciculata and reticulata. Though there was considerable variation in size, shape, and nuclear characteristics, in the main the cells were fairly uniform, large, and polyhedral, with vesicular hyperchromatic nucleus, prominent nucleolus, and well-defined nuclear membrane. The cytoplasm was abundant, granular, and faintly eosinophilic. Vacuolation was a well-marked feature in some areas. Mitotic figures were readily found.

Among aberrant cell forms were (1) multinucleate giant cells, seen fairly often, and (2), rarely, large cells (30 µ), mononucleate or multinucleate, with abundant cytoplasm staining deeply with eosin.

A homogeneous eosinophilic albuminous material separating the cell columns was a prominent feature. In certain areas, notably where cells were arranged in groups, this material occupied cyst-like spaces (fig. 4). Colonel W. F. Harvey and Dr. W. W. Adamson considered that this was due to œdema.

The blood-vessels were large endothelium-lined channels with thin ill-formed walls. Vine's ponceau fuchsin stain was negative.

DISCUSSION

Gynæcomastia is common to all cases described, and it is surprising how this was ignored by the patient in the present case and in those described by Bittorf (1919) and Simpson and Joll (1938).

Except in Holl's (1930) first case (a boy, aged 15, who first noticed a tumour in the right upper abdomen) the breast enlargement was the first sign. In Holl's second case it was associated with considerable pain and discomfort. With this exception, as in the present case, the enlargement was symptomless. The degree of development varies. The most complete is that recorded by zum Busch (1927). The nipples were large and well developed, with increased pigmentation, and a milky fluid could be expressed on manipulation. At biopsy the appearances were typical of the fully developed secreting mammary gland. The present case showed no well-marked enlargement of the nipples, and there was no increased pigmentation or expressible secretion.

Experimentally, Gardner and Van Wagenan (1938), using œstrogens (theelin, theelol, œstradiol benzoate) in male monkeys (*Macacus rhesus*), produced hypertrophy of the mammæ, which on section were of adult type. Though some of the alveoli contained secretion, the picture was not considered comparable with that of the secreting gland; nor was growth of nipples considered to be an index of the degree of breast development. Frazier and Mu (1935) claim to have produced, with repeated injections of œstrogens in male rabbits, enlargement of the mammæ and lactation. Other observers claim that, whereas in the guineapig œstrogenic chemicals alone produce complete development, in the rabbit œstrone and progesterone are required (Turner 1932, Nelson 1936).

Since œstrone, progesterone, and cortilactin (this last capable of producing hypertrophy of the mammæ and lactation) have been isolated from the suprarenal cortex, it seems reasonable to assume that there may be variation in the hormone secreted.

In the present case 17 months after onset of gynæcomastia the penis and testes were large and well developed, in striking contrast to the 3 recorded cases in which comparison is possible. In that described by Bittorf a few months after onset of breast enlargement in August, 1918, there was decrease in size of testes. When examined by Bittorf in April, 1919, the external genitals were small. Approximately a month later Mathias (1922) at autopsy found the testes extremely small, and on section there were hardly any interstitial cells, but there was good spermatogenic tissue. In Holl's second case the penis and testes became progressively smaller after the onset of gynæcomastia. In the case described by Simpson and Joll breast enlargement began in 1932, and in August, 1933, the genitals were smaller.

Experimental evidence indicates that such atrophy may be expected. Thus Frazier and Mu (1935) with repeated injections of œstrogens in male rabbits produced atrophy of the glans penis and testes. Del Castillo and Pinto (1937), using very large doses in adult male rats, produced an increase in weight of the testes with appearance of increased spermatogenesis. This action was in contrast to that produced by smaller doses, which mainly led to atrophy of the penis and testes. This anomalous action, which seems to parallel the œstrogenic action of heavy doses of androgens (Callow and Parkes 1937), can scarcely be accepted as the explanation. A more attractive explanation rests on the conception of Meyer et al. (1932) that œstrone (or testosterone) produces atrophy of the gonads in experimental animals by inhibiting the gonadotrophic activity of the pituitary.

In Simpson and Joll's case the Friedman was negative whereas in the present case, before operation, it was positive. It is conceivable that the excess of prolan could explain the maintenance of size of the gonads.

The negative Friedman, twenty days after the operation, is surprising. There is no pathological evidence which would suggest that the prolan was of other than hypophyseal origin. It is regretted that a quantitative test could not be carried out. In cases of seminoma of the testes associated with excretion of hypophyseal gonadotrophic hormone in excess in the urine, after removal and successful radiation the hormone continues to be excreted in excessive amounts (Beaumont and Dodds 1944).

An interesting case is recorded by McCullagh and Cuyler (1937) of a young woman, aged 17, with adreno-pituitary syndrome (Cushing's) with positive Friedman.

On June 12 outpatient treatment with methyl thiouracil 0·6 g. daily (alone) was started. Within a week the patient reported feeling much better; bleeding had ceased, and diarrhœa was less. B.M.R. +10% on June 24. By June 26 motions were semi-formed and had decreased to one daily.

Methyl thiouracil had been reduced to 0·4 g. daily on June 19, and was further reduced to 0·1 g. daily on July 24. Fig. 1 shows progressive reduction in the number of motions until August 7, when the patient went on holiday. A slight relapse then took place, but from August 28, after her return, until Oct. 16, when methyl thiouracil was withdrawn, only one formed motion was passed daily.

On Nov. 13, after a month without methyl thiouracil, the patient was passing one formed motion daily, and sigmoidoscopy showed a normal mucosa. Weight had risen from 9 st. 5 lb. to 9 st. 9 ½ lb. during treatment.

CASE 3.—A single woman, aged 20, had first had diarrhœa in January, 1946. About 6 fluid motions were passed daily for four weeks, with mucus but no observed blood. Stools continued loose until June, when a relapse of diarrhœa occurred. She was admitted to Addenbrooke's Hospital on Oct. 18, passing up to 5 fluid motions daily with mucus, and the test for occult blood was positive. Barium enema showed loss of haustration in the descending and sigmoid colon. Sigmoidoscopy revealed an inflamed granular mucosa, which bled readily, and much adherent mucopus. B.M.R. +15%. Hb 104%. White cells 11,000 per c.mm. (73% polymorphs).

On Nov. 1 all other treatment was stopped and thiouracil 0·6 g. daily was started. The number of motions fell rapidly (fig. 2), and stools became more formed. Thiouracil was reduced to 0·4 g. daily on Nov. 14 but was restored to 0·6 g. daily on Nov. 19 because of a slight increase in stools. Sigmoidoscopy showed no appreciable change.

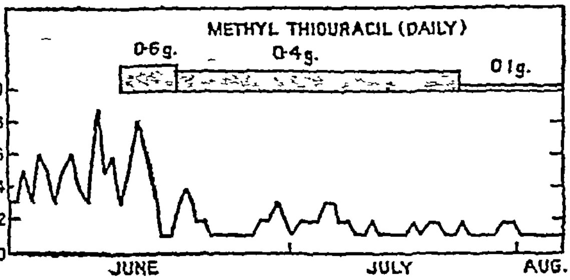

Fig. 1—Chart in case 2.

On Nov. 20 an acute tonsillitis due to hæmolytic streptococcus developed, and thiouracil was withdrawn on Nov. 21 to allow sulphathiazole to be given for the tonsillitis. It was considered unwise to administer both drugs for fear of depressing the leucocyte-count unduly.

Thiouracil 0·6 g. daily was resumed on Nov. 25, and by Nov. 29 one or two semi-formed stools were being passed daily.

CASE 4.—A single woman, aged 26, had been well during nursing training from March, 1944, until December, 1945, when she reported sick with diarrhœa of six weeks' duration. Blood and mucus were passed, and sigmoidoscopy showed patches of swollen hyperæmic mucosa about the size of a shilling high up in the sigmoid; excess mucus was present, and the mucosa bled readily. Hb 47%. Symptomatic and iron treatment improved the anæmia and general condition. On admission to the Middlesex Hospital, under Dr. G. D. Hadley, in April, 1946, she was passing 3–5 motions daily with small quantities of blood and mucus. Hb 89%; weight 9 st. 8 lb.

In June she was worse, having 10–12 motions daily with colicky pain and tenesmus. Laboratory examination of the stools showed no pathogenic organisms or parasites. Sigmoidoscopy (Mr. W. Turner Warwick) revealed a red granular mucosa, which bled readily. Treatment with phthalyl sulphathiazole 1 g. four-hourly to a total of 40 g. produced some improvement, but blood and mucus persisted in 5 or 6 daily motions. Sigmoidoscopy on June 29 showed little change.

In July phthalyl sulphathiazole was given again, together with a mixed vaccine of *Bact. coli* and *Strep. fæcalis*. Definite improvement followed; motions decreased to 3 or 4 daily, were formed, and contained little blood or mucus. The patient went home on August 15 but relapsed quickly and was readmitted to hospital on Sept. 19. Weight 7 st. 13 lb. Hb 84%. Sigmoidoscopic appearances as before. Desiccated pig's ileum was given for two weeks from Oct. 6 without evident benefit (fig. 3).

On Oct. 24 thiouracil 0·6 g. daily was started, and in the ensuing five days motions steadily diminished to 1 or 2 daily. By Oct. 31 the motions were formed, with only traces of blood or mucus, and thiouracil was reduced to 0·3 g. daily. B.M.R. −13% on Nov. 4 (it had been −5% on Feb. 22, 1944, during a survey of normal subjects). Sigmoidoscopy on Nov. 6 showed that the mucosa of the rectum was still friable and bled easily, but the mucosa of the colon above the rectum was much improved and bled only very slightly.

Progress was well maintained until Nov. 19, when thiouracil was reduced to 0·15 g. daily. Within twenty-four hours a slight relapse occurred with 3 or 4 unformed stools and some bleeding. Sigmoidoscopy showed slight but definite worsening of the mucosal appearances, and thiouracil was increased to 0·6 g. daily on Nov. 21. By Nov. 28 improvement was restored. Observation continues.

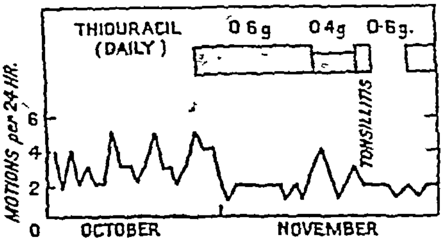

Fig. 2—Chart in case 3.

It is impossible at this stage to do more than point to the immediate amelioration of symptoms after administration of thiouracil in four cases of ulcerative colitis in relapse. It is evident that the normal formation of motions and cessation of diarrhœa in cases 3 and 4 preceded any obvious improvement in sigmoidoscopic appearances, and in cases 1 and 2 it was after four months' treatment that the mucosa appeared normal.

The optimal size and duration of thiouracil dosage must be determined by further trials, but the present impression is that reduction has been too rapid.

It has not been forgotten that ulcerative colitis is a chronic disease characterised by spontaneous and unpredictable remissions, and further long-term observations alone can show whether thiouracil treatment can alter the natural course of the disease.

Sufferers from ulcerative colitis are also readily influenced by spectacular remedies and suggestion, but in these cases thiouracil was given without comment or display of undue interest.

The mode of action of thiouracil can only be a matter for speculation at present, but it is clear that it did not produce frank hypothyroidism in these cases and so render the bowel-transit sluggish. It may well be significant that thiouracil and methyl thiouracil are chemically similar to synthetic 5-methyl uracil (thymine) which Spies et al.[1] found effective in treating the macrocytic anæmia and diarrhœa of tropical sprue. Of particular interest is their observation that stools became semi-formed and reduced to one daily as early as the fourth or fifth day of treatment.

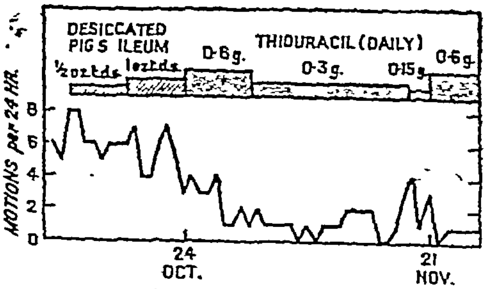

Fig. 3—Chart in case 4.

SUMMARY

Administration of thiouracil in three cases, and methyl thiouracil in one case, of ulcerative colitis in relapse was followed by immediate improvement.

ACUTE INFECTIOUS LYMPHOCYTOSIS IN ENGLAND

ALEX J. STEIGMAN
M.D. Temple
TEACHING FELLOW IN PÆDIATRICS, TEMPLE UNIVERSITY, U.S.A.; FORMERLY CHIEF PHYSICIAN TO THE AMERICAN RED CROSS HARVARD FIELD HOSPITAL UNIT, SALISBURY

ACUTE infectious lymphocytosis was described as a separate clinical entity in American children by Smith (1941). In 1942 three children with this disease were encountered in England and were briefly mentioned by Kilham and Steigman (1942). Besides these three sporadic cases, a small outbreak affecting six children with acute infectious lymphocytosis was seen in southern England in 1942.

Clinical Picture.—A paucity of clinical symptoms and a hyperlymphocytosis are characteristic of this communicable disease. No bacteria or viruses have been isolated, and Smith (1944) found an incubation period of 12–21 days. Biopsy of lymph-nodes (Smith 1944) shows a degeneration of the lymph follicles, with proliferation of the reticulo-endothelium of the sinuses.

Most of the patients seen in the U.S.A. had no symptoms, the diagnosis being established on routine blood-counts in certain convalescent homes, orphanages, &c. The disease is almost entirely confined to children; those few with symptoms have had mild upper respiratory symptoms, low-grade pyrexia, cervical adenopathy, irritability, abdominal pain, and meningeal irritation.

Laboratory examination shows 12,000–100,000 leucocytes, with 50–90% of small mature lymphocytes, and these findings may persist even up to several months. Bone-marrow smears show an increased percentage of small mature lymphocytes. No anæmia or thrombopenia develops, and the heterophil agglutination reaction is negative.

Differential Diagnosis.—This requires the exclusion of infectious mononucleosis (spleen, general adenopathy, angina, fever, *atypical* immature lymphocytes, and a positive heterophil agglutination); lymphocytic leukæmia (enlarged lymph-nodes and spleen, fever, lymphoblasts, development of anæmia and thrombopenia); and pertussis (clinical course and bacteriology).

Transmission.—The communicability of this disease is attested by the institutional outbreaks in the U.S.A., showing a high attack-rate. The exact mode of transmission is not known; treatment is symptomatic.

English Cases.—Three sporadic cases and a small outbreak of six cases were seen in 1942. The sporadic cases, in common with the first American cases of Smith (1941), had mild fever, malaise, fatigue, slight sore throat, and slight cervical adenopathy. The remaining six cases came from one village within a fortnight. The degree of cervical adenopathy was rather striking, but the benign course, protracted lymphocytosis, and the absence of significant bacteria, anæmia, thrombopenia, and heterophil antibodies were typical.

Comments.—This recently recognised disease in children is probably not really new; probably institutional outbreaks, described as mild atypical forms of infectious mononucleosis (Reyersbach and Lenert 1941), were really acute infectious lymphocytosis. Though the disease has been of special interest to pædiatricians, there is no assurance of age limitation, just as there is no assurance of geographical limitation. All cases clinically detected so far have been very benign.

SUMMARY

The clinical entity of acute infectious lymphocytosis was observed in England in 1942.

Paucity of symptoms, benign protracted mature lymphocytosis, and the absence of anæmia, thrombopenia, or heterophil antibodies suggest the diagnosis.

It is hoped that recognition of this disease will lead to further knowledge of its incidence, range of severity, ætiology, epidemiology, and control.

Preliminary Communication

TREATMENT OF ULCERATIVE COLITIS WITH THIOURACIL

WHILE the cause of ulcerative colitis remains unknown it is justifiable to test any empirical remedy, however devoid of logical basis it may appear, and success may give a clue to the ætiology.

The immediate improvement which followed the use of thiouracil in four cases described below warrants this preliminary note, which is intended to stimulate further trials.

CASE 1.—A married woman, aged 37, had had diarrhœa, with blood and mucus, on and off since 1935 and had been treated in several hospitals. In 1936 partial thyroidectomy was performed for Graves's disease, but the ulcerative colitis was unaltered. She attended the outpatient department of Addenbrooke's Hospital in November, 1944, during a relapse in which she passed 6–8 fluid stools daily, with blood and mucus. Sigmoidoscopy showed gross inflammation, with ulcers and bleeding. Hb 56%. She improved slowly with outpatient treatment, but motions were loose and contained excess of mucus for some months. In August, 1945, a severe relapse occurred and sphincter control was uncertain, but the patient refused admission to hospital. Slow improvement followed symptomatic treatment, but her daily life was greatly restricted by diarrhœa.

On March 1, 1946, during another relapse, outpatient treatment with thiouracil 0·6 g. daily was started, without other treatment. A preliminary attempt to measure the basal metabolic rate (B.M.R.) was unsuccessful, as the patient could not remain motionless during the test.

By March 8 the diarrhœa had almost ceased, and on March 12 the B.M.R. was estimated as +12%. On March 14 diarrhœa and bleeding had ceased, and the motions were semi-formed and did not exceed two daily. Thiouracil was reduced to 0·4 g. daily, and steady progress was maintained. B.M.R. +16% on April 25 and −3% on June 3. By June 28 motions were normally formed and rarely exceeded one daily. Sigmoidoscopy showed a virtually normal mucosa with no bleeding or inflammation.

Thiouracil was reduced to 0·1 g. daily on July 26 and withdrawn on Oct. 12. Weight had risen from 9 st. $6^1/_2$ lb. to 9 st. 12 lb. during treatment.

On Nov. 9, after a month without thiouracil, the patient was still passing one formed motion daily but reported the reappearance of some mucus. Sigmoidoscopy showed no inflammation or bleeding but an excess of mucus. B.M.R. +7% on Nov. 14. In view of the reappearance of mucus, thiouracil 0·2 g. daily was ordered, and observation is continuing.

CASE 2.—A widow, aged 54, with three months' history of diarrhœa with bleeding, attended Addenbrooke's Hospital in January, 1942. Sigmoidoscopy showed an inflamed mucosa with ulceration at 15 cm. and ready bleeding. Improvement followed treatment with kaolin and low-residue diet, but stools continued to be loose and frequent. In November, 1944, the patient attended hospital with another relapse, in which 6–10 motions with blood and mucus were passed daily. Sigmoidoscopy in January, 1945, again revealed inflammation and bleeding of the mucosa. Some improvement followed symptomatic treatment.

A further relapse took place in April, 1946. Barium enema showed an irregular mucosal outline and loss of haustration in the descending and sigmoid colon. Hb 90%. White cells 7000 per c.mm. (68% polymorphs). For two weeks the patient passed 3–9 motions daily (fig. 1).

EFFICIENT Hormone Therapy

Fundamental researches on the ovarian and testicular hormones have secured their preparation in pure, highly concentrated, accurately standardised forms suitable for logical and effective use in human therapeutics. Further, their successful syntheses have made adequate quantities available at greatly reduced prices.
British Schering's complete range of reliable hormone products worthily reflects these great advances.

ANAHÆMIN B.D.H.

The Dakin and West
Erythropoietic Fraction of Liver

The clinical efficacy of Anahæmin B.D.H. in pernicious anæmia is remarkable even in the presence of factors tending to limit its activity.
For example, in some cases in which iron is not freely and abundantly available, erythropoiesis induced by Anahæmin B.D.H. may temporarily outstrip hæmoglobinisation, producing a hypochromic anæmia. The provision of an adequate diet during treatment is usually sufficient, however, to provide all the necessary iron and other hæmatinic substances required to produce a balanced and prompt erythropoiesis in response to treatment with Anahæmin B.D.H.
In some instances it is an advantage to provide an extra intake of ascorbic acid in the form of Vitamin C B.D.H., a precaution which tends to ensure the efficient utilisation of protein generally and in erythropoiesis in particular.

Anah/E/107

Hypothyroidism was not induced.

Further trials are needed to determine the necessary duration of treatment and to detect any effect on the natural course of the disease.

Thiouracil is chemically similar to synthetic 5-methyl uracil, which is effective in treatment of the anæmia and diarrhœa of tropical sprue.

I am greatly indebted to Dr. Leslie Cole for access to case 2, and to Dr. G. D. Hadley for details of case 4.

Reviews of Books

Bacteria in Relation to Nursing

C. E. DUKES, M.SC., M.D., D.P.H., lecturer in bacteriology to sister-tutors, King's College for Household Science, London. London: H. K. Lewis. Pp. 186. 12*s*. 6*d*.

NURSES often seem to be taught rules and precepts of paralysing rigidity. In such subjects as hygiene and applied bacteriology—which are so far from immutable that the knowledge of ten years ago is mostly out of date—greater emphasis might be put on guiding principles than on rule-of-thumb about the proper strengths of antiseptics and the cleansing of bedpans. This book is therefore a welcome attempt to put the principles of bacteriology in a form useful to sister-tutors in their lectures. The selection of the material, however, is open to criticism. Bacteriology is, at the same time, a branch of systematic botany, a science in its own right, a handmaid of clinical diagnosis, and the theoretical basis of much of what is called "hygiene." In the education of the nurse the importance of the last far outweighs all the others, and it is regrettable that Dr. Dukes gives so much space to nomenclature and technique; a nurse making media or hunting for tubercle bacilli is wasting time better spent in learning about epidemiology and the spread of infection in wards. It is a pity, too, that he omitted the excellent syllabus of lectures and demonstrations suggested in appendix F of the M.R.C. War Memorandum no. 11. Nevertheless this book fulfils a real need, and, backed by the practical examples of ward and theatre, and, it is to be hoped, by the coöperation of physician, surgeon, and bacteriologist, will enable a sister-tutor to prepare a satisfactory schedule of lectures on the principles on which the control of infection is based.

The Dynamic State of Body Constituents

(2nd ed.) RUDOLF SCHOENHEIMER, M.D., late associate professor of biological chemistry, Columbia University. London: Oxford University Press. Pp. 78. 10*s*.

THE pioneer work of the late Rudolf Schoenheimer and his colleagues, using compounds containing heavy isotopes of carbon, hydrogen, and nitrogen, has led to the conception that the proteins and fats of the tissues, while apparently constant in composition and amount, are in reality perpetually being broken down and resynthesised. This too too solid flesh is in a continual dissolution and thaw. The lipids of the fat depots are undergoing surprising interconversions, while the proteins are in dynamic equilibrium with a pool of amino-acids and α-keto-acids. The use of heavy isotopes has also thrown light on creatine synthesis and provided confirmatory evidence for the Krebs urea cycle. Schoenheimer died in 1941, and the lectures now reprinted were given just before his death, and first published in 1942. The second edition is most welcome, but it might have been as well to have indicated in footnotes where subsequent work has reinforced the evidence presented, and, more particularly, filled in the gaps.

Men, Medicine and Myself

S. VERE PEARSON, M.D. Camb., M.R.C.P. London: Museum Press. Pp. 254. 12*s*. 6*d*.

AN autobiography can never give quite the pleasure to the reader that it does to the writer, but Dr. Pearson's comes near it. He lacks only one quality of the practised story-teller: he is devoid of *Schadenfreude*, he takes no pleasure in the misfortunes of others. That may be because he graduated early in the school of human experience and then took out a perpetual postgraduate course. It was his good fortune to contract tuberculosis just when a revaluation of its curability had set in, and his own life-work covers the whole period of effective treatment. He had the luck too to be sent to Nordrach and his appreciation of Otto Walther after 40 years is a model of what a profile (as it would now be called) should be. Time has not dulled his memory nor allowed woolly sentiment to creep in. With this good start there is hardly a chapter in treatment that has not been illumined by the naturalist's curiosity which is to him the quality most needed in medicine; *that and the* ability to bring home to the lay mind the lesson of healthy living. Moreover he can spell every name except soldanella.

The Principles of Anatomy

(2nd ed.) A. A. ABBIE, M.D., D.SC., Elder professor of anatomy and physiology, University of Adelaide. London: Angus & Robertson. Pp. 273. 12*s*. 6*d*.

IN their revolt against the treatment of anatomy a a routine and unintellectual preliminary subject, teacher are insisting more on knowledge of principles than o memorisation of topographical detail. For many year much of the anatomy taught in medical schools ha been related mainly to the technique of surgery: indeed *the subject has tended more and more to become fi* for a technical school rather than a university.' Yet th intellectual content of this science is considerable an can be developed. Professor Abbie's little book provide the student with an introduction to anatomy and meet a demand. It is short and concise—but perhaps rathe too short, for brevity compels him to be didactic an seemingly uncritical just where it is most necessary t keep the student's mind open and fluid. In a third editio much of the purely descriptive sections (which, in an case, are rather out of place in a book dealing wit "principles") might be eliminated, and those dealin with muscle action, joint movement, and the endocrin system could with advantage be amplified. We woul also plead for more realistic illustrations, which woul give the reader a better opportunity of developing som sense of living plasticity rather than a false impressio of diagrammatic rigidity.

Psychology of Women

Vol. I—*Girlhood*. HELENE DEUTSCH, M.D., assistan psychiatrist, Massachusetts General Hospital. London W. Heinemann. Pp. 312. 21*s*.

AT a time when economic and political decisions tur partly on alleged psychological differences between me and women, many will turn to a book with this title, i the hope of finding in it a statement of the distinctivel feminine attributes, as well as an explanation of thei development. It does not provide such a statement perhaps because it is restricted to girlhood (a second volume will deal with motherhood), and perhaps als because the writer approaches her topic throughout a a psycho-analyst, more intent on interpreting the *dynamic origins of psychological* phenomena *than on* determining what these phenomena are. The psycho-analytical explanation which she sets out with persuasive lucidity centres on "the three essential traits of femininity—narcissism, passivity and masochism." The earlier part of the book examines, in a natural sequence, prepuberty, early puberty, adolescence, and menstruation. Chapters less obviously connected with phases of development follow, having as their theme eroticism, passivity, masochism, the "masculinity complex," and homosexuality in women. The argument is frequently illustrated by case-histories and the recorded conduct *and sentiments of famous persons, like* George Sand and Marie Bashkirtseff. Dr. Deutsch is no doctrinaire psycho-analyst: she was trained by Freud and worked closely with him for years, and has therefore felt free to modify some of his tenets in accordance with her clinical experience. Readers who are not psycho-analysts will find the book sensible and illuminating, and its account of children's fantasies credible. In spite of the pathological material on which it is based, it is largely concerned with the means whereby women grow up well adjusted to their real surroundings, and it gives full weight, among the dynamic influences that form women's personality, to the human and social features of their environment.

THE LANCET

LONDON: SATURDAY, DEC. 28, 1946

Brain-power

THE present man-power shortage is particularly cute in the professions and the upper ranks of indusry, commerce, and the public service This state of affairs is due partly to the seven years' gap in recruitment to some callings and partly to reduction in the number of university students during the war; but t derives also from greater efforts to make industry efficient and to develop the social services. In their atest broadsheet [1] P.E P. estimate that ideally the annual intake to the professions should exceed the pre-war level by 80% in 1946–50, and by 55% in 1951–55. For the next ten years teaching alone will need 23,000 recruits a year; and there ought to be substantial ncreases in the number of nurses, scientists, dentists, social workers, and medical auxiliaries The Barlow Committee has advised that the annual output of pure scientists should be twice the pre-war total of 2500; and there should be about the same increase in technologists. According to the Teviot Committee, the annual output of dentists, which was 340 before the war, should be raised to 800 as soon as possible. By comparison, the medical profession is well served: the Goodenough Committee's 1944 estimate was that a 20% increment would be enough; and the committee held that this could be achieved in six years by a 15% increase on the pre-war annual output of 2000 doctors. Professions in which the pre-war intake will suffice, after the war-time fall in recruitment has been made good, include accountants, company secretaries, and librarians. Those in which present numbers are enough comprise opticians, pharmacists, and possibly also solicitors.

Nobody can say how much demand there will be for university graduates in arts, but P.E P suggest that in order to balance the tendency towards specialisation more young men and women should study the humanities. The risk of encouraging them to take an arts degree is that those who are not absorbed elsewhere may reluctantly turn their hand to teaching, with unhappy results for themselves and for that profession. Much of course will depend on industry's liking for men and women with university qualifications. Owing to the replacement of smaller undertakings by large ones, managers are now usually appointed on their merits, and it has become unusual for a firm to recruit its senior staff in their teens. The Cambridge University Appointments Board found that 73% of employers favour a preliminary university education, because it induces an independent and critical outlook, capacity for responsibility, and social ease. With opportunities for higher education depending more and more on ability, rather than on the parents' capacity to pay, industry may in any case have to look to the universities if it wants brains.

Recruitment to the professions and administration should be planned with three aims: the recruits should be of high quality; the supply should be adjusted to the demand; and there should be fair distribution between the various callings. All this can best be achieved by offering advice and information about careers; by financial aid for suitable people who cannot meet the cost of education; by improving methods of selection; by balancing salaries and conditions between the major callings; and by tapping all sources. Perhaps only the Government can give wide enough publicity to training and prospects of employment; but the Ministry of Labour has not yet taken the steps to issue "reports on trends of employment in relation to higher appointments" which the Hankey Committee recommended. An annual Government prediction, imperfect though it might be, could be no wider of the mark than that of parents who act on rumours of excellent prospects in some particular profession. If the best recruits are to be secured, the opportunity for training must depend solely on ability; and the P.E P. report urges that selection should be both by intelligence, as judged by written examination, and by character, as assessed by interview, some university scholarships being awarded for outstanding personal qualities combined with good intelligence. Factors influencing the intake of recruits to the various callings include the financial rewards, the prospects of promotion, and the conditions of service; but happily there are also other incentives—the interest of the work, the sense of purpose it bestows, the esteem in which it is held, and the scope it offers for initiative and responsibility. These considerations, which do not weigh equally with all young men and women, must be reviewed in occupations where entrants are too few or of poor quality. Thus the McNair Committee recommended an increase in salaries and improvement in the status of teachers, and the Government have lately taken action on similar lines in relation to the nursing profession The Teviot Committee reported that "dental appointments should compare with those available to medical personnel more favourably than they do at present, as regards status, remuneration, and opportunities."

The P.E P. survey underlines the urgency of marshalling the country's brain-power, including that of the refugees now among us. In the final count, however, success will depend on the careful sieving of the nation's youth, the training of all who are suitable, and a balanced allotment between occupations. Here, as in other tasks where resources are scanty, priorities must be decided. Teachers in universities and schools should, perhaps, come first, but other competing demands are not easily settled: what, for example, of the rival calls for pure scientists and doctors? It would be useful to have from time to time an estimate of the relative force of the various claims on our stock of trained intelligence.

Liver-function Tests

THE object of tests of liver function is twofold: to express the extent of liver damage quantitatively, and to aid in the diagnosis between jaundice due to obstruction of large ducts and that due to a diffuse hepatitis. The functions of the liver are many, and the tests based on them are so numerous that the clinician may well wonder which will serve his purpose best. Until recently, evaluation of the tests was based on findings obtained in typical examples of a given disease. If these results were consistent, then similar

ALLEN & HANBURYS LTD · LONDON · E·2

TELEPHONE BISHOPSGATE 3201 (12 LINES) TELEGRAMS "GREENBURYS, BETH. LONDON" antidiuretic effect. From all this VERNEY postulates at there are in the brain " osmoreceptors " which are osely connected by nerve-paths with the pituitary, d, according to tonicity of the blood supplying em, are continually regulating the secretion of e antidiuretic hormone and hence of the urine ow. The exact site of these osmoreceptors is still certain.

The renal mechanism through which the posterior tuitary acts has not yet been revealed by VERNEY'S periments. It has been generally assumed that the tion of the posterior-pituitary secretion is mainly tubular reabsorption, but it remains to be seen hether in addition there is not some alteration of nal circulation like that demonstrated by TRUETA ad his colleagues[1] after various types of nerve imulation. One obvious difference is that the Trueta henomenon disappears after physiological denervaon of the kidney by splanchnic block, whereas osterior-pituitary extract continues to act on the enervated kidney.

Annotations

GUIDE TO BOARDING OUT

RULES always need explanations if they are to be beyed willingly and intelligently. On paper, the egulations for the boarding out of children should have ufficed at least to prevent tragedies in practice, but hey were such dull official reading that they failed to ouch the imagination, or to bring home their responsiilities to some authorities. As a result of Sir Walter onckton's report, in 1945, on the death of Dennis 'Neill, the Home Office and the Ministry of Health ave revised the boarding-out rules, and the work of any local authorities has been reviewed. The new ules have been incorporated in an explanatory memoandum[1] which includes such of the Curtis Committee's ecommendations[2] as can be applied without legislative hanges. Thus the hoped-for " children's officer " does ot yet appear, though the boarding-out visitor is charged ith many of her duties. While the child is in a reception ome the visitor who will later supervise him is instructed o get to know him " as a new friend," and to tell him bout the plans being made for him, describe the fosterome when it is found, and encourage him to look forward o being received into it. She must also get to know he foster-parents as a friend, and must make it clear to hem that they share the responsibility for the child with the local authority, and help them to fulfil their undertakings. The child must be examined by a doctor before being boarded out, and a doctor—who may be the medical officer of the local authority or the family doctor of the foster-parent—must be appointed to attend him when ill, and to examine him yearly. The local authority is responsible for all medical and dental care, and must be notified if the child is seriously ill or hurt; the visitor must make sure that the foster-parents can get into touch with her quickly in case of need. Her attitude to the child is carefully outlined; she must—

> ". . . attempt to find for each child the environment most suited to his temperament and aptitudes, endeavouring to make the first placing a successful and lasting one. She will consider, for example, whether the child in question needs a careful and orderly home, or will be happier where standards are not too rigid; whether he has a stronger preference for town or country life, and whether he is accustomed to, and would miss, the company of other children of his own age. For a dull child she will try to find a foster-home where he will not suffer by comparison with more intelligent children, while for a child of high intelligence or with some special ability she will seek an environment in which his interests and potentialities will be understood and encouraged. Some foster-parents will be at their best with a delicate, nervous, or physically neglected child, while others will be able to understand and manage the active undisciplined boy or the precocious adolescent girl."

This is the sort of guidance which will help boarding-out visitors to recognise their opportunities; but it implies, of course, that they have a wide choice of foster-homes at their disposal. This is not always so, and it is perhaps a pity that the memorandum does not draw attention to another suggestion of the Curtis Committee —that opportunities for boarding out in comfortable middle-class homes should be more fully explored.

The child's needs and wishes are well considered throughout the memorandum. Two pieces of advice serve to show that these are assessed by contemporary standards: the child is to have regular pocket-money and is to be encouraged to learn how to spend it as well as how to save it; and the foster-parent is to let the visitor know when extra financial help is needed " for holidays and for festive occasions, for a bicycle, or for special clothing for games or other purposes."

INFECTIOUS LYMPHOCYTOSIS

IN 1941 Smith[1] in America drew attention to a benign and probably infectious lymphocytosis appearing as an acute or chronic disease in children. The acute cases had a vague and varied symptomatology, but a sharp lymphocytosis was always present. The chronic cases usually followed an infection of the upper respiratory tract; there was a low, persistent pyrexia, vague malaise and anorexia, and often spasms of peri-umbilical pain; a persistent lymphocytosis lasted a month or more; eventually the whole disturbance settled down, and there were no complications. Duncan[2] described an acute case in a girl of 5 years, beginning with acute abdominal pain and rigidity; there was no enlargement of lymphatic glands, liver, or spleen; there were 29,600 lymphocytes per c.mm., sternal puncture showed increased cellularity with 86% lymphocytes, platelets were rather low, but red cells and hæmoglobin were normal; the Paul-Bunnell (heterophile antibody) reaction was not significant. The acute symptoms subsided in a few days, but the pyrexia and the lymphocytosis persisted for a month. Later Duncan[3] reported 2 cases in young adults, and added a morbilliform rash to the clinical picture. Another acute case in an adult—this time a U.S. naval recruit of twenty-nine—is reported by Yuskis,[4] and here again there was a morbilliform rash, mainly on hips, thighs, and legs, and lasting three weeks.

Lorenz and colleagues[5] report 2 more cases in children with peak counts of 47,500 and 58,000 lymphocytes per c.mm., and clinically only mild respiratory affection; sternal marrow was normal in these patients, with no lymphocytosis; the Paul-Bunnell reaction was positive up to a titre of 1 in 80, but this is too low for a diagnosis of infectious mononucleosis. In this issue Steigman reports a small outbreak involving 6 children in one village in southern England; here cervical lymph-glands were notably enlarged and there was protracted lymphocytosis, but all recovered without incident. According to Smith[6] the disease is con-

data in atypical forms of the disease would influence the physician in his ultimate diagnosis. The assessment of tests has therefore rested in the first place on the clinical diagnosis of so-called typical cases, backed by a proportion of observations made at operations or necropsies. Such a basis is not entirely satisfactory, so the correlation of liver tests with the histological appearances of material obtained by liver puncture has a special value. Such a correlation has now been attempted by SHERLOCK.[1]

SHERLOCK has considered serum bilirubin, phosphatase, cholesterol, protein, albumin-globulin ratio, the intravenous galactose test, and the intravenous hippuric-acid synthesis test in the light of liver biopsies. She finds that in hepatitis the serum-bilirubin level parallels cell damage, but in duct jaundice it depends on the degree of duct obstruction rather than on damage to the parenchyma. The hippuric-acid synthesis test shows deficient function in most forms of jaundice, but since this does not parallel the histological picture the test is unsatisfactory. Total protein was also not considered a useful test, though, as SHERLOCK remarks, it is often low in all forms of jaundice; this reduction should provide a useful pointer to the need for plasma transfusion in surgical cases. The albumin-globulin ratio was usually low in hepatitis, from a decrease in albumin with a normal or raised globulin. In duct jaundice the albumin-globulin ratio was also sometimes low, from a decrease in albumin rather than an increase in globulin; this is probably an index of associated cell damage. (Some cases of obstructive jaundice do have a raised serum globulin, probably those in which there is an added infection.) The galactose-tolerance test correlated best with the histological findings, and according to SHERLOCK this test was positive in 15 out of 18 cases of obstructive jaundice. This contrasts with MACLAGAN's[2] 59% of normal results. The difference may be due to the fact that in all SHERLOCK's cases the duct obstruction was complete; the value of the test in partial duct obstruction would then be correspondingly less. In view of this, the bromsulphonephthalein test, less popular here than in the United States, might also be worthy of investigation with histological controls.

Only one test offered some hope of distinguishing between hepatitis and duct obstruction. SHERLOCK found the phosphatase raised, but not above 30 units, in most cases of toxic hepatitis, and above 30 units in nearly all cases of complete duct obstruction. In the latter group it was more or less independent of liver-cell damage; but it may be supposed that in incomplete obstruction phosphatase would often be less than 30 units, so the test would be inconclusive in that difficult group of cases presenting variable jaundice, pain, dyspepsia, and possibly fever. The so-called empirical tests therefore deserve more consideration. In a recent series,[3] the cephalin-cholesterol flocculation test[4] was positive, and the thymol turbidity test[5] greater than eight units in 22 of 29 cases of hepatitis, the 7 weak reactions occurring in cases which cleared up in a week or two. These same tests were negative in 90% of patients with obstructive jaundice, even when this w severe and of three or four weeks' standing associated with moderately extensive metastases. Th few positives were associated with severe infectio very extensive malignant metastases, or long-standi obstruction.

It seems that, apart from the empirical ones, the tests of liver function have little value in the differential diagnosis of jaundice. The serum-bilirubin an galactose-tolerance tests have a quantitative value hepatitis, though their prognostic significance is n great since in most instances the damage indicate whether great or small, is quickly made good. surgical jaundice a positive galactose test m suggest that a given case is a poor operative risk, bu since in the absence of surgery the outlook is dim, th surgeon might well decide to ignore the biochemic findings.

Pituitary Control of Water Excretion

NEARLY fifty years ago it was recognised th extracts of the pituitary gland contain substanc which influence the renal excretion of water, and f the last twenty-five years Prof. E. B. VERNEY, F.R.S has been working on the problem. His Sharpey Schafer lecture at Edinburgh, published in our issu of Nov. 23 and 30, summarised his results, which d much to explain the rôle of the posterior pituitary i the regulation of urinary excretion.

If a dog is given 250 ml. of water by stomach-tub it will usually respond by a diuresis reaching it maximum in about 50 minutes; but if, after th ingestion of water, it is subjected to muscular exercis or emotional stimuli, the rate of water excretio usually falls suddenly, the maximum not bein regained for some 40–50 minutes. The obvious interpretation of this was that the emotion or exercis produced vasoconstriction in the kidney, eithe directly through the nervous system or through th secretion of adrenaline. This interpretation, howeve has been proved wrong: in the first place, the respons occurs equally after denervation of the kidney secondly, the fall in urinary output which follow clamping the renal artery lasts only as long as th obstruction persists; and, thirdly, the fall induce by adrenaline is just as temporary. Where, therefore are we to seek the cause? VERNEY has clearly show that the time-water-output curve can be exactly imitated by giving the animal an appropriate dose o posterior-pituitary extract, and it seems probable therefore that the change in water output following exercise or emotion is conditioned by a sudden outpouring of an antidiuretic hormone by the posterio pituitary gland. This probability is supported by VERNEY's further work. He finds that when an isotonic solution of sodium chloride is injected into the exteriorised common carotid artery the rate of urinary excretion is unchanged; but with hypertonic solutions there is an inhibition of urinary flow of the same form as that obtained by injection of pituitary extract. (With sodium chloride, saccharose, and glucose in an equivalent strength of "hypertonicity" the inhibition is approximately the same: urea, on the other hand, has no effect, because it diffuses easily from extracellular fluid to cells.) If the pituitary gland has been previously removed, or the internal carotid artery has been tied, infusion of hypertonic solutions has

chiefly a nuisance because of the large amounts of human food which they eat or damage.

A pamphlet[2] prepared by Mr. S. A. Barnett for the Ministry of Food stresses the need for a systematic search for rats or mice before any attempt is made to exterminate them. The brown rat follows man in both town and country, living in sewers, factories, and warehouses, and burrowing under hedge-banks and ricks. The black rat, an active climber, is confined mainly to ships and dockyard areas, but is also found inland. The house mouse (*Mus musculus*) adapts itself less well, and usually nests as near as possible to the source of food. In tackling an infested area the nesting sites must be found, then the feeding-places, and finally the runs between the two. Evidence of the last is given by smears left on floors and beams, by droppings, by holes in walls and tooth-marks on metal (rats can, and do, gnaw through lead pipes half an inch thick); also by footmarks, damage to sacks, and disappearance of food. When a rough idea of the size of the infested area has been gained, a sketch map is drawn, and plain bait is laid along the known runs. It may take several days before the bait is accepted; then the poison is added. The bases recommended are damp sausage rusk, sugar meal, bread mash, and soaked wheat. Zinc phosphide 1 in 40, arsenious oxide 10%, red squill powder 10%, and 'Antu' 2% are the chief poisons suggested. Best results are obtained by treating rat-holes in the open, for then cyanide powders can be introduced and the holes securely blocked.

RESEARCH IN MELBOURNE

OUR knowledge of viruses owes much to the Walter and Eliza Hall Institute of Research in Pathology and Medicine, and the director's annual report for 1945–46 again tells of stimulating progress. Following the work of Habel in the United States the Melbourne team has found a simple method of cultivating mumps virus by amniotic inoculation, and mumps and influenza viruses apparently resemble each other in size, in hæmagglutinating behaviour, and in growth on the chick embryo. A suitable technique for titrating antibody by inhibition of hæmagglutination has been worked out and already observations have been made on the sera of convalescents. Mumps virus has been produced in quantity, and formalin-inactivated virus was found to produce significant amounts of antibody when inoculated into young adults. Field tests among school-children are under way and it is hoped that it may yet be possible to produce a single-dose vaccine. Work on the influenza viruses continues, and in October, 1945, the first Australian epidemic of influenza B was recognised.[1] There were few cases among Servicemen or in the general adult population, but half the children at some schools were attacked. Two boys had consecutive attacks of B and A influenza with an interval of 2–3 weeks between—the first time this has been recorded. Active investigation of the phenomenon of red-cell agglutination by virus has already produced results which may have important theoretical and practical implications. It appears that the hæmagglutinin of vaccinia and ectromelia viruses is a stable complex of a phospholipid (probably lecithin) with an antigenically specific product of the virus. It also seems likely that the action of viruses of the influenza group may uncover new antigenic groupings on the cell surface. A better skin-testing reagent has been devised for the diagnosis of herpes simplex; the substance is easy to produce and does not cause non-specific reactions in non-herpetic people.

While much of the report is necessarily concerned with virus work the institute has been active in other fields. In association with American workers North Queensland tick typhus is being studied, and trials on the preventive effect of gamma globulin in measles continue. The department of experimental medicine is tackling the epidemiology of ectromelia in mice, and work has started on the serology of oriental schistosomiasis and malaria. With the opening of a clinical research unit at the Royal Melbourne Hospital there will be new opportunities which Dr. F. M. Burnet, F.R.S., and his colleagues can be relied on to seize.

NEONATAL DIARRHŒA

IN the last few weeks there has been a small but highly fatal outbreak of neonatal diarrhœa in the maternity wards of two hospitals in Leicestershire, and as a result the much milder outbreaks and isolated cases arising elsewhere have been viewed with unnecessary alarm. Figures for neonatal deaths alone are not available, but it is reassuring that the number of deaths from gastro-enteritis under 2 years of age has been no higher than the average in the first 11 weeks of this quarter. Nevertheless, the Leicester experience, in which nearly half the affected children have died, shows that the advent of chemotherapy and the antibiotics, and modern methods of studying viruses, have done little to reduce the case-mortality from this disease, though thanks to improvements in social conditions and infant care generally we no longer see the great epidemics of infantile diarrhœa which swept the country 50 years ago.

Apart from the diarrhœas of known origin which affect children and adults alike—food-poisoning and bacterial dysenteries—and the diarrhœas secondary to parenteral infections, there are at least two forms of infantile gastro-enteritis of undetermined causation prevalent in this country. The first is usually mild (though infants, especially if bottle-fed, may die of it), affects adults at least as often as children, occurs sporadically in hospitals and other institutions over months or even years, and is known to the public as gastric flu. The second is highly fatal, with a case-mortality rising as high as 80–90%, attacks infants in the early weeks of life, appears gradually or suddenly in maternity wards and nurseries, and is the true epidemic neonatal diarrhœa. An example of the mild type is the recent outbreak at Cowley Road Hospital, Oxford. There a mild gastro-enteritis has been prevalent in this temporary maternity home since the beginning of July, but, though 29 babies are known to have been affected up to Nov. 29, when the home was closed, there have been no deaths, and only one baby has been ill enough to need hospital treatment. A significant feature of this outbreak has been an attack-rate of about 60% among the mothers of the affected babies and of 19 out of 21 among the midwives and nurses in the home. The main symptom has been diarrhœa of 2–4 days' duration, and repeated examination of stools has so far failed to reveal any causative organism.

At Leicester General Hospital it seems possible that both types have been present, for there have been sporadic cases of mild diarrhœa among the mothers since early September, and there were 13 severe cases in the babies, 5 of them fatal, in the three months up to Dec. 4. Then within a few days there was a typical explosive outbreak of the fatal type, involving 25 babies in a few days, with 12 deaths.

The cause of both types remains unknown. According to Crowley and colleagues,[1] who studied three outbreaks in 1941, the choice lies between (*a*) infection with an organism of the salmonella or dysentery group, or with a normally non-pathogenic bacterium, or with a pathogenic organism that does not develop well in culture; (*b*) a toxin formed by an organism in the intestine; (*c*) a bacterial toxin ingested with the food; (*d*) a systemic infection with an unknown organism; (*e*) infection with a virus; or (*f*) a protozoon. Those called on to deal with tagious and infectious, with an incubation period of 12–21 days.

There are already several known causes of lymphocytosis in children. Kato pointed out that from three months to four years of age lymphocytes are normally more numerous than polymorphs. A well-marked lymphocytosis has been recorded in whooping-cough, rubella, and mumps after the initial stage. Infectious mononucleosis is common in children, and it is likely that several cases of infectious lymphocytosis have been classified with this disease—for example, Thelander and Shaw's[7] cases of infectious mononucleosis with signs of meningeal irritation, which had a lymphocytosis and negative Paul-Bunnell tests.

Here, then, is a benign almost certainly infectious condition, mainly affecting children, with a very variable clinical picture, sometimes simulating acute abdominal or nervous disease at onset, and sometimes only a mild respiratory tract affection; pyrexia may be protracted, and the blood shows a pronounced lymphocytosis. The Paul-Bunnell reaction is not significant. The differential diagnosis from infectious mononucleosis (glandular fever) may turn on the Paul-Bunnell reaction—not an entirely reliable sign—but the blood picture in infectious lymphocytosis shows only small lymphocytes, with no glandular fever cells or excess of monocytes. In lymphatic leukæmia the patient is much more ill and has a rapidly increasing anæmia, and sternal puncture always shows a massive lymphocytic infiltration.

The prognosis in infectious lymphocytosis is excellent, even if the course is long; no specific treatment has been proposed. The cause has not been identified; it has, as usual, been ascribed to a virus, but no supporting evidence has appeared yet.

NUTRITION IN CEYLON

THE peasants of the Middle East, we are told,[1] "constitute the bulk of the population and . . . produce most of the basic wealth, have few schools, almost no medical facilities, till soil that is not their own, have little purchasing power, and exist under standards that are tragically low." This dismal statement applies also to Ceylon, as is shown in a publication of the department of medical and sanitary services.[2] The basic wealth of the country is derived from the chief exports—tea, rubber, and coconuts. The food that is grown in Ceylon can support barely a third of the population. For her rice Ceylon depends on Burma and for other foodstuffs on India. During the late war, when Burma was occupied and India was facing a famine, Ceylon had to turn to Australia for wheat and other foodstuffs. She has few or no cottage industries to help the peasant population and occupy their time when idle. That the diet is bad there can be no doubt. The state of nourishment is so poor that it is impracticable to use modern European and American standards. Any standards accepted must be based on those ensuring reasonable (not "abounding") health, and often these low standards are not achieved. In 1944, 40% of the families examined were obtaining too few calories (standard, 2000 a day !), 65% too little protein, and 54% too little calcium. Toad-skin and Bitot's spots in the children examined pointed to gross deficiency of vitamin A, and there was evidence of a lack of the B vitamins. The average cost of the diet before the war was 15 cents a day. It had risen to 38 cents in 1944, and nearly two-thirds of the people spent less than this amount. The death-rate is 20 per 1000 and the infantile mortality close on 140 per 1000 live births. Despite these figures the population has risen and is still rising. In no direction are there any grounds for complacency, though there is a little comfort in the fact that things are not as bad as they were in 1937. That the prospects are so unpleasing is not because man is vile but because man, the entrepreneur, has exploited the land and its resources and paid no real attention to the welfare of those w produce most of the basic wealth of the island. It w need a long-term plan of primary, secondary, and ad education, agricultural improvement, supply of medi services, and improvement of the standard of livi with or without a short-term policy of world agricult organisation, to remedy the deplorable state of the pub health in Ceylon.

DOCTORS DIFFER

A BOOK with this title seems in tune with the time and though Dr. Harley Williams[1] deals with histo rather than current differences—and not merely diff ences of opinion but of quality and character— argument is opportune, for he shows that through t differences of doctors medicine grows. There is nothi new about this: the energy generated by opposit moves many things in nature, as British party polit show. But he sets about it with enthusiasm, and h rattling pen and vivid fancy get the circulation going his ten subjects and put them before us as live men though not necessarily quite the men who walked t earth under those ten names. He is deeply read in t debates of Elliotson and Wakley over mesmerism, the lives of old Hugh Owen Thomas and young Robe Jones, of plodding Mackenzie and quicksilver Osler, Macewen and Victor Horsley, and urbane Robert Willia Philip and country-loving Trudeau. His portraits a in the main kindly, even flattering. Sometimes indeed must have shared the perplexity of Mrs. Gaskell fac with the task of writing acceptably of the Bront the great can be so awkward. Is it true, for exampl as Dr. Williams puts it, that "some admiring nurs subscribed secretly and bought a fish-kettle for Macew to boil his forceps"? Or did the sister exclaim, one da "He's been on about that fish-kettle for weeks. F heaven's sake let's buy him one"? If this kind of dou afflicts the reader from time to time it will not impa his enjoyment of stories which revive the times as w as the men. He does less than justice perhaps to Thom Wakley, founder of this journal; and in his relish of t pomposities of Philip he seems for a moment to shed som of his own years and to become one with the irreveren students who enjoyed them.

CONTROL OF RATS AND MICE

THE immense importance of rats and mice as carrie of disease and destroyers of food is perhaps not sufficientl realised in this country. *Rattus rattus*, the "black" o "ship" rat, was the earliest invader of Europe, comin from the East shortly after the Crusades, probably b ship. This settler spread rapidly, but was eventuall almost entirely replaced by *Rattus norvegicus*, the large short-nosed, short-tailed common brown rat, as a resul of a strange revolution in the rat world which took plac towards the end of the seventeenth century. Prof. G. M Trevelyan[1] claims this change-over as the chief caus of the decline of the plague of 1665, because the brow rat did not carry the plague-flea to nearly the sam extent as its predecessor. It is certain that between them they have been responsible for an incalculable number of deaths from plague and typhus, and also for the spread of such infections as rat-bite fever and Weil's disease. The 40,000,000 rats in England at present are

HE STILLBIRTH-RATE IN ENGLAND AND WALES IN RELATION TO SOCIAL INFLUENCES

IAN SUTHERLAND
B.A. Camb., F.S.S.
From the Institute of Social Medicine, Oxford

THOUGH the importance of reducing the death-rate infants is receiving more and more attention, that reducing the numbers of stillbirths, which is just as nportant, has not had nearly so much notice.

Each year in England and Wales there are about 0,000 stillbirths, 18,000 neonatal deaths (of infants nder four weeks of age), and 15,000 deaths of infants ged from four weeks to a year. This total of 53,000 xceeds the combined deaths from heart disease and ancer in persons under sixty years of age, and is more ian double the number of deaths from pulmonary iberculosis at all ages. But it has a biological signifiance not fully indicated by a mere recital of comparave figures, because a child has at birth an expectation f life of some sixty years. These 53,000 are not able fulfil that expectation. They represent a wastage of otential life which can be ill afforded in view of the eclining birth-rate.

During the past forty years, as is well known, there as been a notable decline in infantile mortality. ut this decline has not affected all age-periods ithin the first year equally. The changes that have aken place during the typical period 1930–38, with the orresponding figures for the stillbirth-rate, are as ollows :

	1929–31	*1937–39*	*Decrease*
tillbirths per 1000 total births ..	40·56	38·36	5%
eaths per 1000 live births—			
at ages under 4 weeks	31·78	28·71	10%
" " 4 weeks to 3 months ..	10·68	8·47	21%
" " 3– 6 months	9·28	7·50	19%
" " 6– 9 months	7·91	5·11	35%
" " 9–12 months	7·24	3·74	48%

he bulk of the decrease has taken place at ages from our weeks to twelve months, whereas neonatal mortality nd the stillbirth-rate have shown only slight decreases. t is well recognised that mortality at ages 3–12 months closely associated with bad environmental conditions, nd its decrease has been attributed to improved housing, ygiene, and the educative value of child welfare services. he Registrar-General (1937) has shown that this nortality in 1930–32 was 6·7 in the most favoured social nd economic group in the country, and 31·4 in the least avoured—a figure over 4½ times as great This gradient f the mortality with social class indicates its sensitivity o environmental conditions. But neither neonatal leaths nor stillbirths exhibit nearly so marked a correlaion, and for this reason research is urgently necessary nto the causes and factors predisposing to this wastage f life. This paper is concerned with stillbirths only, ith particular reference to social influences.

STILLBIRTH-RATE IN ENGLAND AND WALES

Stillbirths (which have been notifiable to the local nedical officer of health since 1915) have been registered n this country since July, 1927, in accordance with the Births and Deaths Registration Act, 1926, which includes he following definition : "'Stillborn' and 'stillbirth' hall apply to any child which has issued forth from its nother after the twenty-eighth week of pregnancy and which did not at any time after being completely expelled from its mother breathe or show any other signs of life." Registration was extended to Scotland in 1939. In Denmark stillbirths are also registered and the definition of a stillbirth is the same as in this country.

In 1939 the stillbirth-rate in England was 37, in Scotland 42, and in Wales 49 ; the rate in Denmark was only 26·5. These figures are typical of the differences between the four countries and show that there is room for considerable improvement not only in Wales and Scotland but also in England, where the geographical incidence varies widely. The stillbirth-rate was calculated for each county borough, London borough, urban district, and rural district in England and Wales for the twelve-year period 1929–40, during which time the rate did not fluctuate much in the whole country, and the results are summarised in table I. The first 1½ years of registration were omitted in case some stillbirths initially escaped registration.

The statistical experience in Wales and London affords an interesting contrast. Every region in Wales returns a higher rate than the average for England and Wales, and with one exception (Holborn) every London borough returns a rate below the average. It is clear from the table that the stillbirth-rate does not increase with increasing density of population. In this respect it is dissimilar to infant mortality, and this implies that different causal factors are involved.

TABLE I—UNWEIGHTED MEAN STILLBIRTH-RATES WITH STANDARD ERRORS IN CERTAIN GROUPS OF REGIONS, 1929–40

District	*No. of regions*	*Stillbirth-rate*
London boroughs	28	31·95 ±0·51
County boroughs (England)	79	41·56 ±0·48
County boroughs (Wales)	4	50·68 ±4·73
Urban districts (E)	47	38·31 ±0·65
(W)	12	51·91 ±1·51
Rural districts (E)	47	37·63 ±0·61
(W)	13	62·58 ±0·95

The City and Temples, Rutland and Radnor urban districts, and Middlesex rural district were omitted from the above analysis owing to the smallness of their experience.

The trend in the rate has already been described (Sutherland 1946), and it may be of interest to recapitulate its main features. There was a slight rise until 1932 or 1933, followed by an increasingly rapid decline. This decline has not been halted during the war years ; on the contrary, it has accelerated greatly since 1939, particularly in areas with high incidence. The rate in Wales as a whole declined by 34% between 1938 and 1944. In England the decrease was 27%. There has been a similar decrease in Scotland. Possible causes of this decline are discussed below.

CERTIFIED CAUSES OF STILLBIRTHS

In Scotland, but not elsewhere, a statement of the supposed cause of stillbirth is required on the certificate. Table II gives an analysis of the registered causes of stillbirths in that country in 1943, when the registration procedure had become well established. The table is instructive in two respects : (1) 7% of the stillbirths are inexplicable in terms of present medical knowledge, and 12% are assigned to vague causes, such as prematurity or atelectasis, which terms describe the fœtus but do not explain why the child was stillborn ; and (2) the categories "difficulties in labour" and "accidental hæmorrhage," which include 33% of the stillbirths, represent those which greater obstetric skill may help to prevent. It is thus clear that, though it has an

TABLE II—CERTIFIED CAUSES OF STILLBIRTHS—SCOTLAND 1943

or investigate outbreaks will have in mind the incident reported last year by Brown and colleagues,[2] in which the maternity department of a general hospital appeared to have been affected as a result of a widespread outbreak of minor gastro-intestinal upset in the surrounding neighbourhood. In this instance, as in many others, pathological and bacteriological findings were completely negative. In the outbreak reported by Freedman[3] this year the search for a causal organism included tests for protozoa, but without success except in a single case in which *Giardia lamblia* was isolated. On the other hand, this mild gastro-enteritis in a midwifery block was apparently cured and then controlled by the administration of mepacrine, which was given in doses of 0·1 g. t.d.s. for five days to all residents, including staff and mothers, whether ill or not. The baffling feature of most outbreaks of the mild and severe type is this failure to isolate a causal organism. Only very occasionally can these incidents be ascribed to infection with pathogenic bacteria or protozoa. The most plausible explanation is, of course, that the infecting agents—and there may be several of them—are viruses, of which one at least is relatively non-pathogenic for adults but highly virulent in infants. Another possibility is that the common bacteria of the human intestinal tract—*Bact. coli, Strep. fæcalis,* and the like—may have unsuspected pathogenic potentialities, particularly in the unstable condition of the infant's intestinal tract during the first few weeks of life. Such hypotheses are not easily put to the test in the anxious atmosphere of a maternity ward suddenly threatened with a wholesale loss of infant lives, yet on the satisfactory solution of this problem largely depends the future of institutional midwifery.

As regards prevention in maternity nurseries, Sakula[4] urges breast-feeding whenever possible, strict attention to the hygiene of bottle-feeding, and the avoidance of overcrowding, with an ample staff of well-trained nurses under the supervision of a pædiatrician. But outbreaks do arise even where these precautions are most strictly followed.

CHEST DISEASE IN RAND MINERS

In South Africa measures are being taken to protect the miner against silicosis and pulmonary tuberculosis, and the success obtained is reflected in the report on the work of the Miners' Phthisis Medical Bureau for 1941–44. The much stricter physical selection of recruits for the mines, better ventilation, improved machine drills, &c., have combined to reduce the dust hazard and have halved the incidence of silicosis since 1927. The average length of service underground preceding diagnosis of silicosis has risen from eleven years in 1927 to twenty-one years in 1944, reflecting the general improvement in mining conditions. The miners are examined every three years, after an initial examination when a certificate is given to show that the candidate is free from any disease of the lungs and is in other respects physically fit for underground work. This initial examination is a stiff one, and about 1 in 5 of the applicants are not accepted.

Compensation is run on the following lines. If a miner is found to be suffering from silicosis he is given the choice of taking an award and stopping work underground or continuing to work and postponing the award. If the disease advances in severity from ante-primary or primary to secondary stage he is given a pension. In 1944 the Miners' Union complained that the number of silicotics transferred to the secondary (and therefore pensionable) stage was steadily falling. This seems to have been due to several factors, such as stricter initial examination, improved mining conditions, and fewer cases complicated by tuberculosis—in other words, the state of things is improving. The report says emphatically that silicosis, once contracted, need not necessarily progress towards incapacity and death, and in fact many men certified as silicotics before 1916 are still in the early stages and in relatively good health. That silicosis is not a disease peculiar to those working underground is illustrated by 39 drill-sharpeners working above ground; all these men had X-ray appearances similar to those found in silicosis and arising from the presence of significant quantities of silica and iron oxide dust in the air which they breathed. On the subject of treatment nothing new is said. The Rand docto agree that not enough work has yet been done on t aluminium treatment of silicosis, and their ma emphasis is laid on methods of prevention, such improved dust control.

Tuberculosis is not a common disease among Europe miners in the Rand, and the incidence has fallen 0·7 cases per thousand each year. The association tuberculosis and silicosis, however, is more frequen though this again has dropped, mainly owing to t fact that any miner found to have tuberculosis is oblig to stop underground work. In native workers t incidence of tuberculosis actually exceeds that of silicosi thus confirming the well-known fact that native mine are unduly susceptible to tuberculous infection. N form of mass radiography has yet been introduce though it is likely that this will be done in the ne future.

EDITOR OF THE "BRITISH MEDICAL JOURNAL

At the end of this year Dr. Gerald Horner vacates t editorial chair of the *British Medical Journal,* which l has held since he succeeded Sir Dawson Williams in 192 The doyen of medical journalism in this country, h experience in our small specialty dates from 1911, whe he joined the staff of *The Lancet* as assistant edito From 1915 to 1917 he served with the Royal Army Medic Corps, chiefly in France, and on demobilisation l accepted the post of second-in-command to Dawso Williams. The subsequent years have seen a va increase in the number of the journal's readers, and the are indebted to Dr. Horner more than they know. Hi love of accuracy, his sincerity, and his fairness have s high standards for his fellow specialists, and his whol work bears the mark of a cultivated mind familiar wit the great past of medicine, of which the present i an extension. We can only regret that the continuou labour of marshalling other people's words has too ofte hindered him from giving us his own. Leisure, we hope will free a pen which can write beautifully with ink o almost any pH. Meanwhile on his retirement thousand of colleagues who have called on Dr. Horner or hav corresponded with him will recall particularly his kindnes and his constant desire to help.

We warmly welcome to the editorship Dr. Hugh Clegg who joined the *British Medical Journal* in 1931 and ha been deputy editor since 1934.

THE REGIONS

The Minister of Health has lost no time in defining the hospital regions under the National Health Service Act. On Dec. 20, having examined comments from 200 bodies on the proposals published in our issues of Nov. 30 and Dec. 7, he laid an order before Parliament. Though amended here and there, the scheme in outline remains as it was, and London will be split into four metropolitan areas. Mr. Bevan has told local organisations that though the Welsh region will remain a single unit it will be centred on Liverpool University as well as Cardiff.

Dr. N. M. Goodman, director of the health division, European regional office, Unrra, has been appointed director of field services for the Interim Commission of the World Health Organisation, at Geneva.

[2] Brown, G., Crawford, G. J., Stent, L. *Brit. med. J.* 1945, ii, 524

[3] Freedman, B. J. *Ibid*, 1946, ii, 552.

[4] Sakula, J. *Lancet*, 1943, ii, 758.

It is clearly necessary to test the validity of these ypotheses by seeing if they can explain the pre-war eographical distribution of the rate. In view of the nterplay of opposing factors the best method to employ s that of multiple regression. Two groups of areas were hosen for analysis: the 83 county boroughs in England nd Wales, and the 48 English administrative counties excluding London). For each the multiple regression ested whether the five chosen variables could account or the observed variation in the stillbirth-rate, and measured the importance of each variable independently.

Before the effect of social influences can be assessed, the variation due to biological factors must be allowed for. Many of these factors will make only a very slight contribution. The sex-ratio at birth shows little consistent geographical variation over long periods In 1939 the mean age of mothers giving birth differed inappreciably n the twelve main divisions of the country. Proportions of illegitimate births are small and so cannot cause great variations. The important factor is the parity of the mother, and the main contrast is between primiparæ and multiparæ. The proportion of first births is only obtainable for the twelve main divisions of the country; so some other closely associated index must be used in the multiple regressions. Two possibilities were considered: the crude birth-rate, and the census figure of persons per family. Both give high negative correlations (−0·62 and −0·75 respectively) with the proportion of first births. The crude birth-rate was chosen as more relevant, since the census figure will be disturbed by relations living with the family.

Four variables were used to specify social and economic environment. The sensitivity of the mortality of infants aged 3–12 months to environment has already been illustrated, and so it was used as a general index of poor social and economic circumstances. It is known that unemployment, overcrowding, and poorly paid jobs are all factors relevant to infantile mortality, and indices of these three were used to assess the independent effects of specific aspects of the environment. The five variables were thus taken as:

TABLE IV—WAR-TIME CHANGES IN THE STILLBIRTH-RATE IN ENGLAND AND WALES

Year	Legitimate		Illegitimate		Age of mother			Parity of mother				All multiparæ
	M	F	M	F	20–24	30–34	40–44	No. of previous children				
								0	1	2	5	
1939	39	35	50	44	26	39	68	40	24	31	45	33
1940	37	34	48	48	25	37	66	37	23	28	46	31
1941	36	32	48	43	24	34	63	35	23	28	42	30
1942	34	32	41	41	.	..	..	..	..	.	..	..

Rates for 1941 and 1942 are based on *occurrences*, not registrations.

x_1=Crude birth-rate in 1931.

x_2=Proportion of occupied males over the age of 14 years in social classes IV and V, 1931 (Registrar-General 1934).

x_3=Mortality at 3–12 months (1933–37) (Registrar-General 1937).

x_4=Persons per room in private families, 1931 (Registrar-General 1934).

x_5=Men out of work as a percentage of those occupied, 1931 (Census of England and Wales 1931),

and the multiple regression of the stillbirth rate (1929–40) on these five was calculated The results were:

County Boroughs (England and Wales)

$$Y=38{\cdot}7-2{\cdot}14x_1+32{\cdot}7x_2+0{\cdot}449x_3+13{\cdot}0x_4+0{\cdot}319x_5.$$
$$R=0{\cdot}739 \quad 1\text{-}R^2=0{\cdot}454.$$

Administrative Counties (England)

$$Y=42{\cdot}8-0{\cdot}752x_1+5{\cdot}63x_2+0{\cdot}932x_3-19{\cdot}9x_4+0{\cdot}722x_5.$$
$$R=0{\cdot}711 \quad 1\text{-}R^2=0{\cdot}495.$$

The advantage of these equations is that they afford a means of estimating the stillbirth-rate from the five variables and with a higher degree of precision than if the information given by the variables had not been available. For the administrative counties the estimate is made with 26% more precision, and for the county boroughs with 30%.

In the equations the coefficient of each variable represents the increase expected in the stillbirth-rate for unit increase in that variable, independently of changes in the other variables. Since different units of measurement are used, the relative importance of the coefficients is not indicated by their absolute values. The appropriate test shows that for the county boroughs, the coefficients of x_1, x_2, x_3, and x_5, and for the administrative counties the coefficients of x_3 and x_5, are all highly significant. The others are not significant.

The interpretation of these findings accords with the hypothesis outlined above. In the county boroughs the stillbirth-rate is affected both by unemployment and by the prevalence of poorly paid jobs, both of which are responsible for poor nutrition. Moreover, it is well known that, if food is short, it is the mother who stints herself to feed her husband and family; hence the consequences of unemployment and low pay fall most heavily on her. Physical overcrowding, on the other hand, which is not in itself a cause of malnutrition, shows no relation with the stillbirth-rate. The significant value for the coefficient of x_3 indicates that, apart from overcrowding, unemployment, and poorly paid work, there are other environmental factors affecting the rate which still need investigation. The significant negative coefficient of x_1 indicates clearly that the parity effect masks the importance of the social and economic environment.

In the smaller experience of the administrative counties the picture substantially agrees with that for the county boroughs. The effect of unemployment and of the unspecified environmental factors is plain. It is interesting that the coefficient for the poorly paid work is not significant. This may be due to the fact that in the administrative counties the workers in social classes IV and V are to a large extent agricultural, and so there might not be the same degree of malnutrition associated with low pay as in a more industrial area. Here too overcrowding does not show itself to be important. The coefficient of x_1 is negative, and so, though it is not significant, it serves its purpose of making some allowance for variations in parity.

Antenatal care has not been assessed directly in the above analysis (though x_3 may account for it to some extent). The omission is due more to the difficulty of measuring it than to neglect of its importance. Obviously it is important, as can be judged by a comparison of the stillbirth-rate in Wales with that in London. It was shown previously that the rate in the former was much greater than that in the latter. It is now apparent that the variables used in the regression equations are insufficient to explain this difference, since they give the following predictions for county boroughs in the two areas:

Stillbirth-rate, 1929–40

	Predicted	*Actual*	*Difference*
Croydon	33·4	31·2	−2·2
East Ham	40·1	32·6	−7·5
West Ham	48·5	31·7	−16·8
Cardiff	41·4	47·3	5·9
Merthyr Tydfil	54·5	63·4	8·9
Newport	42·1	40·9	−1·2
Swansea	43·1	51·1	8·0

The three county boroughs in Greater London all have rates less than those predicted, and three of the four *important part to play, obstetric skill is by no means all-important,* and that in 19% of cases the practitioner registering the stillbirth is unable to assign it to a definite *medical cause. This shows that the problem is more* than purely medical or obstetrical. Basic causes must be sought elsewhere, and in this connexion consideration must be given *to the deaths in the first month of life,* because it is generally accepted that the problem of neonatal mortality is allied to that of stillbirths. But *an examination of the certified causes of neonatal deaths* does not help to elucidate the causation of stillbirths, because in early infancy the certification must often be vague.

BIOLOGICAL FACTORS

There are several biological factors affecting the stillbirth-rate, of which the most important are the age and parity of the mother. It is convenient to regard these two together, since a woman's parity is not independent of her age. When the births are classified according to the number of previous children born, the stillbirth-rate within each group shows a well-marked association with the age of the mother. There is a possible slight decrease up to the age of 25, but thereafter the rate increases more and more steeply. When the data are allocated according to the age of the mother, there is in each age-group an appreciable decline between the rates for the first and second child. For the third and subsequent *children born to mothers of the same age the rate shows* a tendency to rise again, but not so high as the rate for the first child, except in the case of young mothers with unusually large *families.* To sum up broadly, *primiparæ* have a higher stillbirth-rate than multiparæ of the same age, and the rates for both increase after the age of 25. A representative series of values is given in table III.

An interesting example of the importance of age and parity is afforded by the statistical experience in the London boroughs. It is generally accepted that in better-class districts the mothers are older and the proportion of first births high, as compared with poor-class neighbourhoods, where the mothers are younger and have larger families. The London boroughs were classified into four groups according to "social index," which is a measure, based on the Registrar-General's five social classes, of the general social and economic level of the borough (Cheeseman 1938). Group 1 comprises Hampstead, Holborn, Kensington, Lewisham, Paddington, Stoke Newington, Wandsworth, and Westminster, which have the highest social indices. Group 4 consists of Bermondsey, Bethnal Green, Finsbury, Poplar, Shoreditch, and Southwark. Groups 2 and 3 are intermediate. The stillbirth-rate in the four groups for three successive triennia are as follows:

Year	*Group* 1	2	3	4
1928–31	35·1 ..	32·9 ..	32·6 ..	30·9
1932–34	33·1 ..	31·3 ..	31·4 ..	31·3
1935–37	33·6 ..	32·3 ..	32·0 ..	30·9

In group 1 the rate is consistently higher than in group 4, with 2 and 3 falling between. The inverse relationship with social status is seemingly due to the age and parity distribution of the mothers being relatively unfavourable in the better-class districts, and favourable to a low rate in the poor-class districts. Any adverse effect of environment is masked by these biological factors.

SOCIAL INFLUENCES

The possible causes of the decrease in the stillbirth-rate during the war years may now be considered. First, such a pronounced decline cannot be attributed entirely to improved obstetrics. Hospitals and maternity homes were overcrowded, there was a shortage of doctors, and those available were overworked. Moreover, it has been shown that, according to the Scottish data, improved obstetrics could only affect about a third of the stillbirths. Yet the decline in Wales has been of this ord and there is no evidence that Welsh obstetrics becam perfect during six years of war. Secondly, the decl is not due to changes associated with the biologic factors, because table IV shows that it has affected bot male and female births, legitimate and illegitimate, and mothers of all ages and parities. *Figures later tha* those quoted are not yet available. A decline so universa in all respects must have a universal cause.

TABLE III—STILLBIRTH-RATES FOR LEGITIMATE SINGLE BIRTH BY AGE AND PARITY OF THE MOTHER, ENGLAND AND WALES JULY, 1938, TO DECEMBER, 1940

Age of mother (years)	Number of previous children				All multiparæ	All paritie
	0	1	2	5		
20–24	29	18	22	26	19	26
30–34	54	26	30	38	31	38
40–44	*105*	*56*	*55*	*67*	*64*	*68*
All ages	39	24	30	46	32	36

This cause must therefore be sought in the social an economic environment of the pregnant woman. In view of the rather static character of the stillbirth *rate and neonatal mortality during a period when the* was an appreciable decline in the mortality in the late ages of infancy—a decline commonly ascribed to improve*ment in the general environment*—this may seem *a priori* an unprofitable line of inquiry. But it must be appreciated that the word environment connotes a *multiplicity of factors, some adverse, some (like the age* parity effects) favourable to a reduction in the stillbirth-rate. For that reason the influence of the individual factors must be studied separately. The necessity fo doing so is indicated by the findings of Baird (1945), in Aberdeen, who has clearly shown that not only obstetric care but also social environment influences the stillbirth-rate, and *that social environment is, if anything,* the more important.

In many respects the environment of the expectant mother deteriorated during the war. The strain and anxieties of life increased, particularly in the towns, with overcrowding, bombing, queueing, separation of families, and other additions to the housewife's duties and responsibilities. Moreover, married women worked in industry *to a greater extent than ever before.* All these are factors which might well be expected to have increased the rate. To offset these influences are two which have improved notably and universally for the pregnant woman: general nutrition and antenatal care. Priority milk and eggs, supplementary vitamins, and, later in the war, other extra rations were made available universally, for the first time, to the expectant mothers of all income-groups; and, *pari passu* with this official concern of the Ministry of Health and Ministry of Food for maternal nutrition, went increased earnings, the expansion *of antenatal clinic facilities,* and widespread propaganda for their use. It is tempting to conclude that the foregoing factors were mainly responsible for the decline in the stillbirth-rate. The nutritional standard set throughout the country would explain why the worst areas of the country have shown the most *improvement and, as a consequence, have rendered the* experience of the whole country more uniform. Improved *nutrition would raise the general level of health of the* mother and make her better able to support the growing fœtus. Further, the investigation of the People's League of Health (see *Lancet* 1942) has shown *notable decreases* in the incidence of toxæmia consequent on nutritional improvements. It has been shown above that in Scotland 10% of stillbirths are attributable *to this cause.*

isolated and is isolating represent only a small percentage of the protein in the aqueous muscle extract used, which in turn represents only a fraction of the total muscle proteins.

ENZYMATIC SYNTHESIS OF POLYSACCHARIDES

In his second lecture Professor Cori described how he had synthesised in vitro such natural products as glycogen and amylose, and showed that the products were in every way identical with the natural compound. Using the techniques of high polymer chemistry, he worked out in great detail the kinetics, autocatalytic behaviour, &c., of the reactions involved. He was able to determine the chain length of the polymer molecule at every stage of the synthetic process, as well as the necessary chain length of the initiating molecules.

At the end of this lecture Professor Cori touched on the wider significance of his work, when he discussed the old question, “What makes these metabolic cycles go round?” In other words, he brought up the question of the hormonal control of carbohydrate metabolism, which, he said, “has hitherto yielded inconclusive results.” At his stage he divulged some new and highly interesting ndings. As is well known, glucose enters the “meta-blic mill” by virtue of its phosphorylation to glucose-6-phosphate, called the Robison ester. This reaction is catalysed by the enzyme hexokinase. When insulin and other hormones have been added to such an enzyme system in the past, no conclusive results could be obtained. In Professor Cori’s laboratory muscle tissue was taken from animals which had been rendered diabetic by means of alloxan, and it was found that here the phosphorylation of glucose was impaired and that this inhibition could be countered by insulin. Furthermore, since it is known from the work of Houssay that the diabetes of depancreatised animals is ameliorated by removal of the pituitary, Professor Cori tried the effect of pituitary extracts on the hexokinase system. The results showed that some pituitary extracts inhibited the hexokinase system even further and that this effect was again counteracted by insulin. Much the same applied to adrenal extracts, as was to be expected from the work of Long on the influence of the adrenal cortex on diabetes. Here at ast seems to be the long-awaited linkage between hormones nd enzymes in the field of carbohydrate metabolism.

BRITISH EMPIRE CANCER CAMPAIGN

ANNUAL GENERAL MEETING

THE annual meeting of the Campaign was held in London on Dec. 19, under the chairmanship of Viscount Hailsham, the acting president. A message was received from the Duke of Gloucester, the president who welcomed the Campaign’s continued activity.

Sir Stanford Cade moved the adoption of the annual report which, he said, is the 23rd of a consecutive series recording nearly a quarter-of a century’s progress in cancer research. The Campaign correlates controlled research, helps individual workers in recognised centres, disseminates knowledge, and helps to destroy the fear of cancer. To further these aims a *British Journal of Cancer* is shortly to be published.

The best yardstick of progress is the yardstick of mortality. Deaths from cancer in accessible sites and in ome internal organs have decreased, while in other ites the peak of the rise has not yet been reached. Some may think that cancer research is about to become lely a State responsibility. Nothing, however, is rther from the truth. Pioneer and research work will still depend on the efforts of individual research-workers; and further work and further progress will depend on the subscribers.

The motion was seconded by Mr. E. R. B. Graham.

The Campaign’s Garton medal and prize of £500 was presented to Prof. E. L. Kennaway, F.R.S.

The annual report will be summarised in a later issue.

MR. R. LINDSAY-REA, surgeon to the Western Ophthalmic Hospital, London, has received a presentation from his colleagues on his retirement. He has been 25 years on the staff of the hospital.

In England Now

A Running Commentary by Peripatetic Correspondents

IT is often said to be impossible to work for higher degrees while serving in the Forces. This is nonsense. With an Army grading in surgery and no civilian specialist qualifications, I realised that I must seriously set to work for my Fellowship. And when the demobbing of specialists was slowed down this became still more important. I started to work for the Primary in March, and managed to confound the examiners seven months later. During this time I was stationed in Germany, and had no fewer than ten moves. Only once or twice was I able to visit the anatomy department at Hamburg University. What dissection I did was in the operating-theatre and the post-mortem room.

Bones were a difficulty at first. I foolishly sold my skeleton when, as a student, I thought I had finished with anatomy for ever. But steadily a skeleton was assembled. One bone was found here, another there. The skull had been used in festivities at a sergeants’ mess party; it had a glass eye and a fine set of false teeth. A first thoracic vertebra, with two first ribs attached, was very nice—but the ribs were both upside down. The wrist was articulated with its various bones in the right order, but there had been no attempt at correlating the various surfaces. In the foot the third and fourth metatarsals were interchanged. And the fibula! I had always regarded it as the most aggravating of bones, but this one baffled me completely. I puzzled over it for fully half an hour before I realised that it was articulated upside down. So much for German thoroughness. One whole suitcase had to be sacrificed to my skeleton, and clothes only served to stop the bones from rattling. It accompanied me wherever I went, and many a batwoman must have paled at the gills when she came to do my unpacking.

Books are a menace to cart around, especially tomes like Gray, and Best and Taylor. For the anatomy I made two real finds. One was Frazer’s *Osteology*, and the other Jamieson’s *Illustrations*. I had used neither before, and both helped immensely. After reading Frazer, in particular, I think I can appreciate how Keats felt when first he looked into Chapman’s Homer. For the applied physiology I found Best and Taylor a scholarly work, beautifully written and a real pleasure to read.

The exam itself was quite straightforward—fair papers and gentlemanly vivas. But it strikes me as very hard that you cannot get special leave for exams, or at least have your privilege leave extended. It certainly benefits the Army to have its specialists well qualified. But no matter—I shall soon be demobbed, and I had a glorious bonfire of all my notes.

* * *

Nothing is more distasteful to the doctor than to have some outside body pressing him to act, or appear to act, otherwise than in his patients’ interests. Hence the uneasiness at the official-appeals for tightening up milk priority certification. Some of us disagree with the Ministry of Food when it doubts whether the sickness-rate has risen to the extent suggested by the increased number of milk priority certificates issued. But if there is really not enough liquid milk to meet all the priority certificates and to give the general public its 2–2½ pints a week it is doubtless right to revise the list of people receiving certificates. Otherwise there may be more sickness and a greater need for certificates next spring.

The doctor may feel there is no-one whom he can conscientiously take off his list, but if, whenever he is asked for a milk certificate, he says to himself: “Does Mr. Y really need as much milk every day as Mrs. X gets in a week?” perhaps something may be done. Take two actual cases. There is a woman who had a mastectomy four years ago and has had no recurrence of growth; she leads an active life and eats a normal diet; she never calls for professional attention, but she still asks for her milk certificate and still gets it, presumably because she is thin, nervous, and vociferous—especially vociferous. She does not even like the milk, and shares it with her cat, but she insists on having it, although she needs it less than many old people who have to exist on their bare rations. Then there is another

Welsh county boroughs have rates considerably in excess of expectation. It seems legitimate to assume that the difference can only be accounted for by better antenatal care and supervision, coupled with better obstetrics.

One example will indicate the value of antenatal care. In Newcastle-on-Tyne before the war an analysis was given each year by the medical officer of health of the births to mothers who had attended the antenatal clinics. Averaged over the period 1932–38 the stillbirth-rates were as follows:

Among mothers attending antenatal clinics ..	34·9
Among the residual births to Newcastle residents ..	40·6
Among the residual births registered in Newcastle..	64·3
Among births delivered by midwives	26·0

In view of the fact that the antenatal clinics would tend to attract an undue proportion of primiparæ the contrast between the first two figures is notable. The third figure indicates how hospitals tend to attract difficult cases from outside the town. No conclusions should be drawn from the last figure, since it will probably be biased in favour of births to multiparæ. It may be noted, however, that the rate is lower than that for all multiparæ in England and Wales given in table I. Though table I relates to a different period, this comparison under-estimates the actual difference in view of the secular trend.

Finally, it is instructive to ascertain the number of stillbirths which could be prevented if the rate in the country as a whole could be reduced to the level in London, which has the lowest stillbirth-rate, despite an age- and parity-distribution less favourable than the average.

If the rate in England and Wales in 1944 had been equal to that in London there would have been 2100 fewer stillbirths. This may seem a small saving, but it must be remembered that in this year there were better care and better nutrition for the pregnant woman than before the war. Wise administrative action had in all probability levelled many of the social and economic inequalities which existed in pre-war years, and was responsible for the considerable reduction in the average stillbirth-rate. But further saving is possible in view of the statistical experience in Denmark. If the stillbirth-rate in England and Wales in 1944 had been 19·4—the Danish figure—the number of stillbirths expected would have been 14,900. The actual number recorded was 21,200. There would thus have been a saving of 6300 lives Thus the lives of 2000 children would be saved if the incidence in London applied to the whole country, and a further 4000 by attaining the Danish level. Added to this, there would be an appreciable reduction in neonatal deaths, since the problem of neonatal mortality is allied to that of the stillbirth-rate.

SUMMARY

The task of reducing the numbers of stillbirths is important in view of the falling birth-rate. Stillbirths have apparently shown themselves resistant to the improving environmental conditions which have been to a great extent responsible for the decline in infantile mortality between the ages of 3 and 12 months.

The general features of the stillbirth-rate in this country between 1928 and 1944 are surveyed. There was wide geographical variation before the war, and there has been a pronounced and universal decrease throughout the war which has reduced the variation considerably. Attention is called to the low rate in London and the high rate in Wales. The stillbirth-rate is closely related to the neonatal death-rate.

The certified causes of stillbirths are examined. About a third are due to factors which improved obstetrics should help to prevent, and a fifth are attributed to vaguely certified or unknown causes.

Biological variations in the rate are examined, the mo important being the relations with the age and pari of the mother.

It is shown that neither obstetrical nor biologic factors can explain the decrease in the rate during th war, and the influence of antenatal social factors is considered by means of multiple regression. When biologic variations are allowed for it is found that the rate i the county boroughs is not affected by overcrowdin but is influenced by the degree of unemployment an proportion of poorly paid workers. This agrees with th suggestion that the war-time decline is primarily due t the improved nutritional opportunity and the care th has been taken of the pregnant woman. A simil analysis for the English administrative counties shows th rate there to be correlated with the degree of unemplo ment but not with overcrowding or with the proporti of poorly paid workers. In both cases there is eviden that other environmental factors are important. Th value of antenatal care is stressed and demonstrated.

To reduce the stillbirth-rate to the Danish level wou cause the numbers of stillbirths in England and Wal to drop from 21,000 to 15,000, with a correspondin decrease in neonatal deaths.

I wish to thank Miss Marie Lindhardt, of the Dani National Health Service, for information concerning sti births in Denmark; and Dr. W. T. Russell for helpf criticism.

CARBOHYDRATE METABOLISM

ON Nov. 25 and 29 Prof. Carl Cori delivered tw lectures at the London School of Hygiene on the fundamental work done in his department at Washingto University, St. Louis, on the intricate mechanism o *carbohydrate metabolism.*

ISOLATION OF CRYSTALLINE ENZYMES FROM MUSCLE

The first lecture dealt chiefly with the study of three ke muscle enzymes—phosphorylase, aldolase, and phosphoglyceraldehyde dehydrogenase. All these enzymes wer prepared in a pure crystalline state in very good yield This work involved a gigantic intellectual as well a physical effort, but Professor Cori made it all sound ver easy. In discussing the preparation of the enzym phosphorylase he described, for example, how all attempt to crystallise this enzyme failed until it was found tha it was essential to filter off a small precipitate which appeared at one stage of the purification of the enzym from the original muscle extract. A further investigation of this precipitate led to its characterisation a an enzyme which split off the coenzyme, adenylic acid from the phosphorylase and thus prevented the successfu isolation of the latter enzyme. The "small precipitate" was termed a P–R enzyme, and its properties, which ar trypsin-like, are being used as a tool in investigating the mode of linkage between coenzyme and apoenzyme.

After describing these "adventures in carbohydrate metabolism," as Professor Cori called them, he outlined his plans for further work in this field, especially research involving the use of isotopes. From such work Professor Cori expects answers to such questions as "What is the average life-time of an enzyme?" and "Where do the enzymes come from?" Already it appears, from detailed amino-acid analyses of these pure crystalline enzymes, that two enzymes which occupy neighbouring positions in the "Cori cycle" differ widely in amino-acid composition. It therefore seems unlikely that all these enzymes originate from some "protein-pool" and acquire their specificity merely by some physical rearrangement of the protein molecule. By simple arithmetic Professor Cori showed for what a vast number of enzymes there is room in a tissue-like muscle, since all the enzymes he has

ROVISION FOR A MAJOR BURNING DISASTER

SIR,—The recent tragedies at Atlanta and in Canada, ith that of 1942 in Boston, involving between them more an 600 lives, must have set many wondering about the ssibility of a similar happening here. A writer in e *Times* has pointed out that in many of our large towns e are by no means adequately protected by stringent e-escape regulations.

On the medical side the disturbing question arises: ow many of our hospitals could cope effectively with a dden influx of, say, 5 to 50 severely burned patients? n the Boston incident the two chief hospitals had to deal ith 170 cases.) Would they be able to mobilise within hour or so the personnel to set up immediate plasma drips" for the bad cases? Would they have the large antity of plasma or serum required, the sterile gowns, asks, and towels, the dressings, the penicillin cream, d—perhaps most important of all—the extra nurses eded for the frequent administration of fluids and other od to those with bandaged hands and faces?

Our experience here is that the care of one severely rned patient may demand as much as 4–5 hours of e time of a skilled medical man and a nurse during the t 24 hours; and we not infrequently use as much as 0 grammes of penicillin cream, and 10 20 crêpe ndages, for a single case. This adequate care during e first 24 hours is all-important both for the saving of e through the critical "shock period" and for the later ocess of repair of the burned tissues. The resources of y hospital are likely to be severely strained to provide ch care.

I would suggest that the necessary arrangements for ch an emergency should be thought out and agreed and periodically revised by hospital staffs. The ganisation of one or more burns centres in our larger ties would certainly be in the best interests of the many ctims of everyday burning accidents as well as the ctims of such occasional major disasters

LEONARD COLEBROOK.

Medical Research Council Burns Unit,
Birmingham Accident Hospital.

TREATMENT OF TUBERCULOSIS

SIR,—Some of the statements made by Dr Houghton d Dr. Corrigan (Dec. 14) ring so true and have such gnificance that they demand repetition. For example

> "The patient who enters a modern sanatorium can no longer contemplate a period of tranquillity and freedom from personal anxiety, but must face a series of collapse therapy measures beginning perhaps with phrenic nerve interruption or artificial pneumothorax or pneumoperitoneum, and advancing, in the case of failure of these measures, towards the irreversible procedure of thoracoplasty. The effect of this protracted ordeal on apprehensive personalities is often disastrous, and some patients are put to too much emotional strain during treatment As we are well aware, this has a deleterious effect on the progress of the disease.
>
> "Apart from surgery, the great benefits of which we do not wish to decry, the very facts of diagnosis and subsequent segregation constitute a severe threat to morale A long stay in hospital, involving perhaps many months of rest in bed, does not tend to reinforce confidence, and sometimes creates more problems than it solves To these emotional stresses may be added domestic and economic problems. *Long rest in bed is useless without a measure of mental serenity.*"

These observations may be viewed in the light of r. George Day's remark (Nov. 16) about his first three ses:

> "In all three the disease was diagnosed early and brought early to treatment without avail."

e know that healthy girls can enter sanatoria as urses, contract the disease, and die of it in the institutions eant to cure, in spite of treatment from the earliest ecognisable sign.

Dr. Day's fourth patient had "bilateral excavation d a family history riddled with phthisis"; yet without y sanatorium or other recognised treatment "the vities, one of which used to be the size of a tangerine range, had disappeared completely. There was plenty of firm-looking scar tissue but no sign of any activity." And he asks the question, "Why did she do better than our sanatorium patients?"

In considering the disadvantages of sanatorium life, do we not tend to gloss over segregation—the separation from healthy minds and bodies? Apart from loneliness, there are many other deleterious factors, particularly those occasioned by shortage of staff and food restrictions.

The number of people whom radiography shows to have recovered from tuberculosis, without any institutional care, is at least ten times the number treated for active disease. Presumably a proportion of those nowadays treated would eventually get well by themselves.

Are we right then to submit patients to the conditions described in the first-quoted paragraph? Would it not be better, particularly in view of the shortage of nurses, beds, and equipment, to do as we have done with other infectious diseases—treat the patients at home? They would at any rate be spared the "disastrous and irreversible procedures." Without the use of amphetamine, and with the lessened mental disturbance, we might see more of the tuberculous deriving the benefits noted in Dr. Day's fourth case.

Birmingham. JAMES F. BRAILSFORD.

FATAL USE OF A DANGEROUS UNIVERSAL DONOR

SIR,—The conclusions reached by Dr. A. D. Morgan and Dr. G. Lumb (Dec. 14) are, in my opinion, based on slender evidence.

In the first place, no real evidence is offered that the onset of anuria was not due to the administration of sulphadiazine; the absence of sulpha crystals in the urine does not eliminate this possibility. In this hospital we recently had a case of sulphadiazine suppression of urine (transfusions of blood had not been given before the onset of oliguria), in which crystals of sulpha compounds were not demonstrated in the small amount of bloody urine passed, although tests for soluble sulphonamides were positive.

The reaction reported by Morgan and Lumb may have been due to the transfusion of blood; but the investigations mentioned were not sufficient to warrant the conclusion that the reaction was due to high-titre α agglutinins in the donor's blood acting on the A antigen of the patient's cells. The following criticisms are made:

(1) There is no mention of any blood-transfusions previously given to the patient. Presumably none were known, but if any were ever given the possibility of isoimmunisation against the Rh antigens must be considered. In this connexion, the diagnosis of the patient as Rh-positive should be considered as unreliable, since the test was made on blood removed from the patient after the transfusions of blood.

(2) Occasionally severe reactions are due to the rare but naturally occurring antibodies against the blood factors M, N, Lutheran, or P. No tests for these antibodies are recorded.

(3) The writers report that *no agglutination* occurred when the patient's cells were tested against his own serum. This test alone may not determine in-vivo sensitisation of the patient's cells unless the absence of an "incomplete" antibody had been demonstrated—e.g., by using Coombe's anti-human globulin serum.

(4) The patient's serum, removed after the onset of suppression, was tested against the cells of the three group-O donors, with negative results. However, in severe transfusion reactions due to the action of the patient's antibodies on donated cells, the specific antibodies are rapidly removed from the circulating plasma and absorbed by the donated cells. Ten days or so later these antibodies reappear. Hence the in-vitro testing of suspected cells against the patient's serum during the first few days following the transfusion-reaction often gives negative results. Positive results may be obtained with a pretransfusion sample of serum or with serum obtained 14 days or more after the transfusion, should the patient survive; but the tests should be performed in tubes at 37° C, as well as at room and refrigerator temperatures. The preliminary

woman who had an operation twenty years ago, she says vaguely, for dropped stomach ; she lives in a hotel where she enjoys a better diet than the average householder, including such luxuries as chicken and duck. Her difficulty is that she cannot digest the badly cooked vegetables and she needs ascorbic acid ; but she has had throughout the war, and still has, a milk certificate. Her doctor is now retiring and the partner will no doubt drop her off the list. These are cases drawn at random from two different districts ; they give a hint that, if the ruling for postoperative cases were strictly followed, there could be some saving of milk for more deserving people.

The Ministry of Food has apparently discovered that the overall consumption of priority milk works out at 12 pints a week per head—nearly 2 pints a day for every holder of a certificate. Yet the only category entitled to receive 2 pints a day is that of gastric and duodenal ulcer. These cases while in hospital actually receive 3 pints a day, but patients with priority certificates for 1 pint receive only 4 oz. of milk a day if on meat diet (at least, they do in our hospital, and Sister says it's "regulations.") So it does not seem that hospitals can be held responsible for the surprising average. Can the milkman, perhaps, throw some light on the mystery ? It is not unknown for him to go on delivering the daily pint, when supplies are good, long after the certificate has expired. He is within his rights, when he has surplus milk, but this is a possible source of confusion to the statistician.

The shortage of milk has been made harder to bear by the *Drink More Milk* campaign of pre-war days, when milk-bars sprang up in the towns, and we all became milk-conscious. There were a few heretics who maintained that man, like other mammals, does not need milk when the period of suckling is over, but in view of the undeniable benefit to children and adolescents who take extra milk such arguments were easily refuted ; and vague biological analogies are never very convincing. So many more people were drinking milk when war began, and the deprivation has consequently been more keenly felt.

Could not this demand be partly met by providing more powdered, evaporated, and tinned milk for the ordinary consumer ? The easily assimilable milk proteins and the mineral salts are especially needed by two non-priority classes—(1) the sick whose certificates have not been renewed, thanks to the tightening up, or who do not come under any of the priority categories, and (2) the aged, whose digestions are failing and who receive no concessions or consideration under the rationing scheme. During the war there was sufficient shipping to carry food to troops in every part of the globe. Could not civilian needs for preserved milk be treated now with the same urgency ?

* * *

There is undoubtedly a whole field of medicine yet to be developed as an adjunct to broadcasting technique—from the "syrup codein. phosph." draught of your coughing correspondent to a couple of 'Seconal' capsules or a shot of intravenous pethidine for the really anxious or distraught. Broadcasting in a discussion recently I felt that we were all greatly in need of some kind of premedication—alcohol being forbidden as too erratic in its effects. For the gabbler of the party (myself) phenobarbitone would have been insufficient ; even a preliminary course of thiouracil to reduce me to myxœdema would have failed to allay my desire to get it over as quickly as possible. Headache—in a stuffy studio—was another complaint, though whether ergotamine tartrate or intensive psychotherapy would have made the better cure must await further research. A mild anorexia was evident only in the female member of the group, but I am convinced that hyperchlorhydria was universal and I am surprised that more ulcers do not perforate during or after broadcasts.

At present the B.B.C. makes no provision for ante-transmission neuroses. Perhaps in future we shall be vetted and doped according to well-established methods and our E.C.G.s and E.E.G.s taken throughout the broadcast. So far the only practical idea has come from a medical colleague who suggests the routine use of bismuth and tinct. opii for a complaint from which our group all suffered.

Letters to the Editor

THE B.M.A.'s DECISION

SIR,—Those who are leading the British Association are men of good intent who really that what they do and think is best both for the and the people. But a time has come when they alienating the sympathy of laymen from us.

It would almost seem that we are being led by a office file that first began to write itself in 1911. Histor has repeated itself. Then as now the council h bargained with a Welshman and had got as much reasonable men could expect. Then as now son wanted more and gained control. Then as now moderat men went, or were driven, out of the council to be replac by the less moderate. And then began that policy of t "strike that is no strike," though no-one but a memb of the B.M.A. council can understand it. It has becon the pigeon-holed policy of the association, brought out fro time to time with enormous preparation, to be put in threatened action and then to fail. It failed in 1911-1 It failed again in 1922–23 or thereabouts. It will fa again now, because the strike is not the weapon of a intellectual profession.

The present policy of the B.M.A. may, for the momen conform to the herded will of the medical profession; does not conform with the profession of the art of med cine. That is progressive, and with the change of tim changes also.

Perhaps the lamentable result of this plebiscite ma be turned to advantage by eliminating the presen Negotiating Committee. This has been absorbed by th B.M.A.—a thing that is likely to happen to committee organised by it. As the largest medical organisation it i asked to collect a number of persons to represent th profession. This it does, and does well ; and then i stultifies its own work by absorbing them to itself an so fixing upon them the policy of its office file. It di so many years ago with the Insurance Acts Committee and though laymen are wrong in supposing that i controls the G.M.C. the fact remains that the directl elected representatives on that body are nowadays th nominees of the B.M.A. council.

The members in the divisions can readily be induced t vote in the way their leaders wish. And so it come *about that a few people of fixed views,* with an abl secretariat, are able to dominate a great profession.

London, S.E.1. T. B. LAYTON.

THE NEGOTIATING COMMITTEE

SIR,—On the average, members of the Negotiating Committee have been qualified for close on 35 years. One of the members has actually been qualified more than half a century. Comment is needless. How differently this committee would be viewed if it contained a majority of younger men—from recent ex-Service personnel down even to fourth-year students. SENEX.

BLOOD-PRESSURE IN PREGNANCY

SIR,—Are many general practitioners spending sleepless nights puzzling over the increasing frequency of hypertension in pregnant women ? True, one is told that it is more apparent than real, and that hypertension is commonly found nowadays only because doctors are more conscientious in taking blood-pressures than of old.

This is scant comfort, and I don't think it is correct. In my own practice I examine some hundred maternity cases yearly, and during the last six months it has been unusual to find a blood-pressure below 136 mm. Hg systolic and 70 mm. diastolic ; the majority vary between 140/90 mm. and 150/100 mm. It isn't my sphygmomanometer, for in despair I have sometimes sent a case to a consulting obstetrician and his readings have been similar. In most cases the blood-pressure starts to rise about the twentieth week and then remains stationary ; but it does rise and I don't know why. The patient, of course, blames the bread : I hesitate to do that.

It would be interesting to know if others have any views on the subject. E. A. NETTELL.

Exmouth.

ROVISION FOR A MAJOR BURNING DISASTER

SIR,—The recent tragedies at Atlanta and in Canada, ith that of 1942 in Boston, involving between them more an 600 lives, must have set many wondering about the ssibility of a *similar happening here.* A *writer in* e *Times* has pointed out that in many of our large towns are by no means adequately protected by stringent e-escape regulations.

On the medical side the disturbing question arises: ow many of our hospitals could cope effectively with a dden influx of, say, 5 to 50 severely burned patients? n the Boston incident the two chief hospitals had to deal ith 170 cases.) Would they be able to mobilise within hour or so the personnel to set up immediate plasma drips" for the bad cases? Would they have the large antity of plasma or serum required, the sterile gowns, asks, and towels, the dressings, the penicillin cream, id—perhaps most important of all—the extra nurses eded for the frequent administration of fluids and other od to those with bandaged hands and faces?

Our experience here is that the care of one severely rned patient may demand as much as 4–5 hours of e-time of a skilled medical man and a nurse during the t 24 hours; and we not infrequently use as much as 0 grammes of penicillin cream, and 10–20 crêpe ndages, for a single case. This adequate care during e first 24 hours is all-important both for the saving of fe through the critical "shock period" and for the later rocess of repair of the burned tissues. The resources of ny hospital are likely to be severely strained to provide ch care.

I would suggest that the necessary arrangements for ch an emergency should be thought out and agreed n and periodically revised by hospital staffs. The rganisation of one or more burns centres in our larger ities would *certainly* be in the best interests of the many ictims of everyday burning accidents as well as the ictims of such occasional major disasters.

LEONARD COLEBROOK.

Medical Research Council Burns Unit,
Birmingham Accident Hospital.

TREATMENT OF TUBERCULOSIS

SIR,—Some of the statements made by Dr. Houghton nd Dr. Corrigan (Dec. 14) ring so true and have such ignificance that they demand repetition. For example:

> "The patient who enters a modern sanatorium can no longer contemplate a period of tranquillity and freedom from personal anxiety, but must face a series of collapse-therapy measures beginning perhaps with phrenic-nerve interruption or artificial pneumothorax or pneumoperitoneum, and advancing, in the case of failure of these measures, towards the irreversible procedure of thoracoplasty. The effect of this protracted ordeal on apprehensive personalities is often disastrous, and some patients are put to too much emotional strain during treatment. As we are well aware, this has a deleterious effect on the progress of the disease.
>
> "Apart from surgery, the great benefits of which we do not wish to decry, the very facts of diagnosis and subsequent segregation constitute a severe threat to morale. A long stay in hospital, involving perhaps many months of rest in bed, does not tend to reinforce confidence, and sometimes creates more problems than it solves. To these emotional stresses may be added domestic and economic problems. *Long rest in bed is useless without a measure of mental serenity.*"

These observations may be viewed in the light of Dr. George Day's remark (Nov. 16) about his first three cases:

> "In all three the disease was diagnosed early and brought early to treatment without avail."

We know that healthy girls can enter sanatoria as nurses, contract the disease, and die of it in the institutions meant to cure, in spite of treatment from the earliest recognisable sign.

Dr. Day's fourth patient had "bilateral excavation and a family history riddled with phthisis"; yet without any sanatorium or other recognised treatment "the cavities, one of which used to be the size of a tangerine orange, had disappeared completely. There was plenty of firm-looking scar tissue but no sign of any activity." And he asks the question, "Why did she do better than our sanatorium patients?"

In considering the disadvantages of sanatorium life, do we not tend to gloss over segregation—the separation from healthy minds and bodies? Apart from loneliness, there are many other deleterious factors, particularly those occasioned by shortage of staff and food restrictions.

The number of people whom radiography shows to have recovered from tuberculosis, without any institutional care, is at least ten times the number treated for active disease. Presumably a proportion of those nowadays treated would eventually get well by themselves.

Are we right then to submit patients to the conditions described in the first-quoted paragraph? Would it not be better, particularly in view of the shortage of nurses, beds, and equipment, to do as we have done with other infectious diseases—treat the patients at home? They would at any rate be spared the "disastrous and irreversible procedures." Without the use of amphetamine, and with the lessened mental disturbance, we might see more of the tuberculous deriving the benefits noted in Dr. Day's fourth case.

Birmingham. JAMES F. BRAILSFORD.

FATAL USE OF A DANGEROUS UNIVERSAL DONOR

SIR,—The conclusions reached by Dr. A. D. Morgan and Dr. G. Lumb (Dec. 14) are, in my opinion, based on slender evidence.

In the first place, no real evidence is offered that the onset of anuria was not due to the administration of sulphadiazine; the absence of sulpha crystals in the urine does not eliminate this possibility. In this hospital we recently had a case of sulphadiazine suppression of urine (transfusions of blood had not been given before the onset of oliguria), in which crystals of sulpha compounds were not demonstrated in the small amount of bloody urine passed, although tests for soluble sulphonamides were positive.

The reaction reported by Morgan and Lumb may have been due to the transfusion of blood; but the investigations mentioned were not sufficient to warrant the conclusion that the reaction was due to high-titre α agglutinins in the donor's blood acting on the A antigen of the patient's cells. The following criticisms are made:

(1) There is no mention of any blood-transfusions previously given to the patient. Presumably none were known, but if any were ever given the possibility of isoimmunisation against the Rh antigens must be considered. oses of 10 mg. or intramuscular doses of 50 mg. of iamine might be sufficient to precipitate masked defi- encies of other factors, and this may be the explanation f the suddenly increased weakness and ataxia in both ses.

At a time when the chemical industry produces creasingly potent synthetic vitamins at decreasing rices, and when both public and profession are becoming ore and more vitamin-conscious, it would seem that the terdependence of the several factors—at present mainly emonstrated in the B group of vitamins—deserves reater consideration.

London, W.1. Z. A. LEITNER.

CORONARY DISEASE

SIR,—In support of the possible infective basis of oronary artery occlusion, Dr. G. E. Beaumont (Dec. 14) ites the development of leucocytosis and a raised erythro-yte-sedimentation rate (E.S.R.) in this condition. Surely t is generally accepted that these are manifestations of he myocardial infarction and the resulting destruction f tissue. I would suggest that any simple aseptic farct in any site may, if large enough, lead to the evelopment of fever, leucocytosis, and a raised E.S.R., nd that therefore such phenomena following an occlusion do not in any way indicate an infective process.

Department of Pathology,
University of Bristol. M. SYMONS.

A MORAL PROBLEM

SIR,—The issue is not so much whether the results of he German investigators should be published as whether cience can ever truly profit from crime.

There can be no scientific honesty without moral ourage, and no clear reasoning without freedom of hought. In the atmosphere of crime, lies, and suppression that pervaded Nazi Germany no true scientist could have produced anything worth while. And how could one trust the scientific findings of people so devoid of judgment and reasoning that they believed their government's propaganda that Poles, Russians, Frenchmen, and Jews were criminals who should die an abominable death because of their race?

No doubt some points in their findings might be of use to investigators. But there is a far more valuable lesson to be learnt from publication—namely, that with all their unheard-of facilities these Nazi criminals could make few observations of importance.

Mitcham. MAX B. KLEIN.

SIR,—Perhaps it is fortunate for Mr Mellanby that the slaughter of prisoners is not yet British custom. He has thus been spared decision in that moral dilemma which he finds so perplexing.

If the Germans obtained important information from their investigations he would think it right to use their findings. In fact, however, we have no reason to believe that anything of value was ever discovered by the Germans by these methods. The privileges of study in the prison camps were granted, in the main, as rewards for faithful service, to Party officials and S.S. men, and to leaders of the Hitlerjugend and Hitlermädel. By 1939 repeated purges of the medical profession had ensured that its surviving members should be honoured confederates in such company.

The experiments consisted largely in elaborate sexual assault. The atmosphere of pseudo-science in which the proceedings were staged, to the accompaniment very often of the music of Wagner and Beethoven, was no more than a ritualistic addition designed to lend piquancy to the occasion.

These things are not widely understood. Mr. Mellanby cannot be expected to assess with justice circumstances of which, by implication from his letter, he has no conception. Nevertheless, in appearing to discern dignity in monstrous evil, he does some small further injury to the outside world's already sufficiently feeble appreciation of what it is that has been destroyed in Germany.

Dartford, Kent. I. McD. G. STEWART.

Public Health

Rag Flock, Bedding, and Upholstery

THE bedding and upholstered articles on which people spend about a third of their lives should be clean. The Interdepartmental Committee on the Rag Flock Acts point out[1] that this country lags behind some others in the legislation and precautions adopted to ensure that the filling materials are free from infection and dirt. They received evidence that rag flock, the commonest filling material used, is still being made from dirty rags. One witness said that some of this material is collected by rag-and-bone men who go round from house to house with a barrow or cart and collect from tips and dumps. These men are usually employed, or paid for what they bring in, by dealers. No material, however dirty, is refused. "It calls for little imagination," said the witness, "to realise that most of these rags must of necessity contain much infection, filth, and excreta." In the factories where the rag flock is made the cleansing processes vary within fairly wide limits according to the facilities available and to the zeal and scrupulousness of the manufacturers. The provisions of the Factories Act as regards health and cleanliness apply of course to registered factories. In some places the rags are steeped in cold water, and sometimes hot water with or without detergents is used. In others the rags are subjected to agitation while being steeped, the temperature of the water being raised by steam under pressure. A number of rag-flock factories, however, have no washing plant and presumably the rags are not washed at all. To make rag flock the dried rags are disintegrated by passing them over a rapidly revolving cylinder studded with steel teeth. This is a dusty process, the dust being controlled more or less effectively by exhaust ventilation. Sometimes the rags are sprayed with small quantities of oil to reduce the loss of fibre in the dust, but the use of oil has the disadvantage of binding some of the dirt into the flock.

The present legislation dealing with the manufacture and use of rag flock is contained in the Rag Flock Act, 1911, and the regulations made under it in 1912; the Rag Flock Amendment Act, 1928, and the Public Health (London) Act, 1936, sec. 136. The latter section re-enacts the provisions of the previous Acts and regulations in substantially the same form. The Act of 1911 makes it an offence for any person to sell or have in his possession for sale flock made from rags or to use it for the purpose of making upholstery, cushions, or bedding or to have it in his possession unless it conforms to a prescribed standard of cleanliness. This standard was prescribed under the regulations of 1912 and consists of what is known as the "chlorine test," by which the amount of chlorides removed by washing under specified conditions does not exceed 30 parts of chlorine in 100,000 parts of flock. The duty of administering the Act and regulations is placed on the local authorities. The 1928 Act defined the term "flock manufactured from rags" and limited its application to material produced from woven, knitted, or felted materials.

RECOMMENDATIONS

The committee could find no direct evidence that disease or ill health is being transmitted by unclean filling materials used in bedding and upholstery, but they think it safe to presume that disease might arise from the use of such materials. It is possible that the use of unclean filling materials is a contributory cause of certain respiratory ailments in which the sources of infection are not known. In any case the development of the public-health services is based on the attainment of cleanliness. The committee regard the present legislation dealing with the making and use of rag flock as inadequate to protect the public. In their opinion there should be a statutory prohibition against the sale of unclean rag flock intended for use as a filling material. All premises on which rag flock is made or stored or is used in making bedding, upholstery, or other household routine cross-matching of patient's serum and donor's cells performed on a tile may sometimes not show this incompatibility.

---

[1] Cmd 6866. London: H.M. Stationery Office. Pp. 36. 9d. The committee was appointed in 1936 with Lord Merthyr as chairman, and its medical members were Dr. W. G. Clark and the late Dr. G. H. Pearce.

(5) A transfusion reaction due to high-titre α agglutinin in group-O blood given to a group-A patient would be unlikely or impossible if the patient's serum normally contained soluble A factor. This is usually the case when the saliva contains the A substance, but no mention is made whether the patient was a "secretor" of A substance; nor was the presence of this substance in the patient's serum apparently investigated. This possibility must be eliminated before concluding that the anuria was due to the high-titre α agglutinin in the donor's plasma.

Pathological Department, Military Hospital for Head Injuries, Wheatley, Oxon.

DANGERS OF CALCIFEROL

SIR,—Your leading article of Dec. 14 is timely. We were on the point of writing to suggest that some restriction should be placed on the sale of calciferol. A sense of harmlessness surrounds the idea of vitamin therapy, but, in fact, the highly concentrated preparations may be most dangerous.

We have had some two hundred patients, mostly suffering from lupus vulgaris, under treatment with calciferol over the past twelve months and intend in due course to publish our observations and the results of our investigations. We feel, however, that the incidence of toxic symptoms is so high, and the character of the symptoms so serious, that some warning is necessary in view of the freedom with which calciferol is being presented to the profession and the public.

Symptoms of intolerance arise as often and seriously in adults as in children. A high proportion of these cases present the picture of an abdominal emergency, and the symptoms may deceive the élite. Urgent admission to hospital and operation may follow.

In all our cases of intoxication there has been a considerable increase in serum calcium and a raised blood-urea. Though the total calcium may not be raised in those with mild symptoms, the diffusible calcium is invariably raised. Macrae has recently stressed the importance of watching the blood-sedimentation rate. In animals we have found that calciferol severely damages the kidneys.

It seems desirable that all patients on calciferol should have written instructions to stop treatment and report immediately should they experience any untoward symptoms, and especially such abdominal symptoms as pain, anorexia, sickness, and extreme constipation. With such precautions, and careful and regular observation and biochemical control, serious harm is not likely to occur.

That calciferol is of importance in the treatment of lupus vulgaris and that it will play an important part in the control of the problem of lupus is quite certain. That it is of value in other ills is unproven, and it should not be prescribed in high dosage except with proper control.

PERFORATED PEPTIC ULCER TREATED WITHOUT OPERATION

SIR,—Mr. Hermon Taylor (Sept. 28) states that the conservative treatment of perforated peptic ulcers has a mortality of 14%, and that surgical intervention should be reserved for late cases—patients with gastric dilatation from pyloric stenosis—and for those who have ingested a large quantity of fluid just before or after the perforation.

Signs suggesting perforation are usually pronounced, but sometimes, as laparotomy shows, these signs appear without a perforation. At other times the so-called *gedeckte* (subacute or sealed) perforation, which was first described by the Viennese surgeon, Schnitzler, is found; here the ulcer is sealed off by adhesions to a neighbouring viscus, either before or immediately after the perforation. The symptoms are less acute, and the peritoneal signs are more or less limited; in many gas may be found under the diaphragm. In such cases, if there is no deterioration in the first few hour
defer operation until all signs of peritoneal
have disappeared.

In other cases the perforation is not sealed
adhesions; the opening remains free and uncovere
seen at laparotomy on late cases.

As we know, the contents of the stomach are
by virtue of its hydrochloric acid, so that perit
does not develop if the ulcer is closed by adhesio
suture. But if the opening remains, the highly inf
contents of the intestines can discharge into the
toneal cavity by antiperistaltic waves.

A surgeon expecting every perforated ulcer to be s
off by adhesions will be disappointed, especially if h
not the wide experience of Mr. Hermon Taylor;
failure means the death of the patient.

The late results of simple suture of a perforated
are not satisfactory; in 91% of these cases a ne
recurrent ulcer is found later, so that the patie
exposed to the risk of a second operation or a
perforation.

Therefore with perforations seen after 12–24 hou
perform a partial gastrectomy; the mortality is
in the first twelve hours and 12% in the second, b
many of these late cases peritonitis has already develo
After 24 hours a suture operation only is perfor
In all of Mr. Taylor's cases a partial gastrectomy w
have been undertaken.

MALNUTRITION IN RELEASED PRISONERS-OF-WAR AT SINGAPORE

SIR,—The admirable analysis of malnutrition
Dr. Mitchell and Dr. Black (Dec. 14, p. 855) and si
recent studies make a further advance in the evalu
of the causal relationships of single and multiple defici
states.

Signs of vitamin deficiency have often been r
several weeks after the patient has been on a full n
tious hospital diet with vitamin therapy. Cases 1 a
(Mitchell and Black) illustrate this point. Both pat
had peripheral neuritis with tingling, numbness, red
sensibility, and loss of superficial reflexes, with
degree of amblyopia. Both patients were given 6
pound vitamin tablets daily (containing altoge
150 mg. ascorbic acid, 60 mg. nicotinic acid, 6
thiamine, and 6 mg. riboflavin), while case 1 was g
in addition 10 mg. of thiamine daily intravenously
case 4 received 50 mg. of thiamine daily intramuscul
After nine days' treatment case 1 became sudd
weaker in the legs with gross ataxia of both arms
legs, while case 4 was suddenly unable to walk or w
The authors mention that similar observations
described by Spillane and Scott [1] and also by Clarke
Sneddon.[2]

During recent years the importance of the interrela
ship between various factors of the vitamin-B group
been urged several times, subclinical latent deficie
becoming manifest after energetic treatment of
obvious deficiency. Pellagrins have been reporte
showing signs of beriberi, or what has been describe
riboflavin deficiency, after treatment with nico
acid [3, 4]; signs of pellagra [5] and of riboflavin deficien
have appeared after treatment with thiamine. Richar
demonstrated experimentally on rats that excess of t
mine may easily precipitate a masked deficiency
pyridoxine. Mitchell and Black's case 1 had 10 mg
thiamine intravenously; case 4 had 50 mg. intramu
larly. As far as could be ascertained, the cases repo
by Spillane[8] and by Clarke and Sneddon [2] were
given generous doses of thiamine, although these writ
especially Spillane, tried to balance the diet of t
patients carefully. It is reasonable to submit tha
grossly undernourished chronic cases daily intraven

eement with the Joint Advisory Dental Council.—Mr. es Griffiths replied: As part of the agreement the Joint visory Dental Council advised members of the profession erally to resume the practice of accepting insured persons treatment in accordance with the Dental Benefit Regulans. It has always been a matter for each individual dentist decide whether or not he will accept patients on this basis, d a certain number of dentists have never participated in e service. I am aware that certain dentists have indicated at they are not following the recent advice of the advisory uncil but I have no reason to believe that this is the attitude f any large proportion of dentists.

Future of King's Fund

Sir John Graham Kerr asked the Minister of Health what, der the new National Health Service Act, were the intentions f the Government with regard to the King Edward's Hospital und.—Mr. A. Bevan replied: The new Act does not alter any f the powers and duties of the Fund under its own statute. I pe that the Fund will continue its very valuable work—in hatever forms it may feel to be appropriate to the new rvice.

Obituary

WILLIAM JOB COLLINS

K.C.V.O., M.D., M.S. LOND., F.R.C.S.

Sir William Collins, whose death was announced in ur last issue, died on Dec. 12 at the house in Albert errace, Regent's Park, where he was born 87 years ago nd where his father, Dr. W. J. Collins, practised. His other, Mary Anne Francisca Treacher, belonged to the Huguenot family of Garnault. The family took pride in their distaff descent, and some twenty years ago Sir William served as president of the Huguenot Society in London. From University College School he went with a Jeaffreson exhibition to St. Bartholomew's Hospital, where he graduated M.B. in 1881, winning the university scholarship and a gold medal in obstetrics. After holding house-appointments at Barts he became in 1884 demonstrator in anatomy. Before he qualified in medicine he had already taken his B.SC. with honours in physiology, and he was unable to accept the current tenets of medicine unquestioningly. s early as 1881 he was asking in our columns how far e commonly accepted notions of the specificity of isease should be modified by the doctrine of evolution:

Press Portrait Bureau

> "The common ancestry of specific diseases, once recognised, would do much to remove the hard and fast line so often drawn between diseases and diseases in textbooks, and dissertations, but of which nature knows nothing."

his theory he later elaborated in his essay on *Specificity d Evolution*, which Herbert Spencer, to whom it was edicated, declared opened the way to a "considerable form in pathology," and in *The Man v. Microbe* (1903). erhaps it was his background of heterodoxy which flected him from what promised to be a brilliant rgical career: for after taking his M.S., M.D., and R.C.S., all in 1884 and 1885, he turned to the specialty ophthalmology. He joined the staff of the Royal ye Hospital and Western Ophthalmic Hospital as rgeon, and was also ophthalmic surgeon to the National emperance Hospital. He published a monograph on taract in 1897, and during the war of 1914–18 he scribed several interesting cases of gunshot wounds the eye. As Doyne medallist and lecturer in 1918 he oke on Ophthalmology and the War. A senator of s university for over 30 years, he twice held office its vice-chancellor.

From his conception of the specificity of disease sprang s belief that diseases should be fought outside the body d not within it. With this belief went his eagerness to improve the environment of the people, and he was among the last of the great Liberal Victorian social reformers. One of his heroes was Edwin Chadwick, whose biographer he later became, while Florence Nightingale and Sir William Morris, founder of the Charity Organisation Society, were his friends.

For many years a member of the London County Council, he was its chairman in 1897. In 1904 he was chairman of its first education committee, while its ambulance service was started almost entirely through his efforts. In 1909 a departmental committee and the L.C.C. itself recommended that the Metropolitan Asylums Board should provide the service. Sir William, a member both of the committee and the council, opposed this suggestion, and when neither would accept his views, nothing daunted, he introduced into Parliament, to which he had been elected in 1906, a Bill to confer the powers on the L.C.C. The Commons accepted it in preference to a Bill based on the recommendations of the departmental committee, and the L.C.C. reluctantly accepted its new obligations. The service was started in 1915 under the control of the chief officer of the fire brigade. Sir William became a vice-lieutenant of the county of London in 1925 and was also a justice of the peace.

An experienced and able negotiator, he sat on many royal commissions, notably those on vivisection (1906–12) and on vaccination (1889–96). An ideal chairman, he presided over a select committee on the hop industry (1908), the departmental committee on accidents to railway servants (1914–19), the Conciliation and Arbitration Board for Civil Servants (1917–18), and the Sussex Agricultural Wages Committee (1920–39). To bodies more nearly allied to medicine he was an equally valued counsellor, and he was chairman of the Chadwick Trust, member of the council of the King's Fund, president of the Sanitary Inspectors Association, and from 1899 to 1928 secretary of the League of Mercy. He was asked to help in the formation of the Central Council for District Nursing, and his skilful handling of the eager but sometimes conflicting interests involved brought order and system to the work of the council, of which he was chairman for more than thirty years. When he retired in 1944 the position of president was specially created for him. His work for the council is an example of his value as a coördinator. Through his contacts with the L.C.C. and with the King's Fund, the work of district nursing came to be linked both with the municipal and voluntary hospitals, while as trustee of the City Parochial Charities he was able by his excellent advocacy to direct funds to its exchequer.

As plenipotentiary for Great Britain he attended three international opium conferences held at The Hague between 1911 and 1914. His interest in the problems of addiction linked him to the Medico-Legal Society, over which he presided from 1901 to 1905, and his *Ethics and Law of Drug and Alcohol Addiction* which appeared in 1916 was a balanced survey. He believed in the "potency for good of reduced facilities for tippling," but he advocated restriction and not prohibition.

"I knew Sir William Collins well," Lord Addison writes, "and he was one of those in the old days who stimulated interest in many of us in public affairs as well as in surgery. Looking back on the time of my own acquaintance with him I should say that this fact was outstanding. In those days his wide public interests and sustained activities placed him almost in a class by himself, I should think, amongst surgeons." He was knighted in 1902 and appointed K.C.V.O. in 1914. His acute brain and statesmanlike grasp of affairs served many good causes without a trace of self-interest, and he served them all well.

JOHN ERNEST ALBERT LYNHAM

M.D. BELF., M.R.C.P., F.F.R.

Dr. J. E. A. Lynham, consulting radiologist to Mount Vernon Hospital, died on Dec. 14. He was educated at Queen's College, Galway, where his father, Dr. J. I. Lynham, was for many years professor of medicine, and at Queen's College, Belfast, where he graduated in medicine in 1907, taking his M.D. four years later. After two years as assistant medical officer at the Woolwich Infirmary he was in 1911 appointed assistant superinfurniture should be registered by the local authorities, who should be given power to suspend or revoke registration if the necessary conditions are not being satisfied. There should be the right of appeal against any decision of a local authority to the Minister of Health or the Secretary of State for Scotland. Rag-flock manufacturers and wholesale dealers should be required to keep records showing the destination of each consignment of flock sold by them and the date of sale. Bedding and upholstery makers using rag flock should also keep records of the sources of supply. Local-authority officers should be empowered to inspect the records and to enter any registered or unregistered premises to take samples for analysis. They should also have power to enter any premises on which finished articles of bedding or furniture are sold or offered or exposed for sale; the cost of repairing any damage caused by the opening up of the finished articles should be met by the local authority unless a conviction ensues. Any retailer of bedding and upholstery should be able to plead as a defence a warranty given by the maker in legal proceedings taken against him.

Most of the recommendations about rag flock should, in the opinion of the committee, be applied to all other filling materials such as kapok, feathers, down, wool, and various vegetable fibres. Whatever the filling material used there should be compulsory labelling of each article of bedding and upholstery so that its origin might be traced. Legislation controlling the use of filling materials should also be applied to the coverings and linings of upholstered articles. Evidence had been given to the effect that dirty sacking, tainted meat wrappers, and other contaminated articles are sometimes used as linings of bedding and upholstery. It is added that the filling materials of stuffed toys should have the same standard of cleanliness as that laid down for upholstered articles and bedding. The committee do not think it practicable to prescribe in detail the washing and sterilising processes to be applied in the manufacture of rag flock. In their opinion the proposed system of registration and inspection by the local authority will bring about the necessary standards of cleanliness. The "chlorine test" is regarded as unsatisfactory because it cannot be assumed that flock containing a high proportion of soluble chlorides is necessarily dirty, and further, the standard of 30 parts of chlorine to 100,000 parts of flock is too easily reached without adequate cleansing. The Fenton test at present under investigation by the British Standards Institution, in conjunction with the trade, is the best available test for rag flock and animal fibres. It is necessary, however, to devise other tests for cotton flocks and some other vegetable fibres.

The committee urge that new legislation on this subject should not be too long delayed because it is a matter which touches closely on the daily lives of the whole population.

Infantile Diarrhœa in Maternity Homes

The Registrar-General's figures for the first eleven weeks of the December quarter do not show any notable increase of mortality from enteritis and diarrhœa. Thus in 126 great towns (including London) the average number of deaths of children under 2 years of age per 1000 births for the December quarter 1946 to date was 5·8, whereas the comparative figure for the same period of 1945 was 6·8.

The outbreaks of gastro-intestinal illness recently reported from maternity homes and other institutions in various parts of the country are not all of the same clinical type. Up to date the most serious appears to have been at two hospitals in Leicestershire with between 40 and 50 cases among infants and 23 deaths. In its high case-mortality and relative lack of associated illness in adults this outbreak resembles incidents already recorded in the United States[1] in 1939 and in England[2] in 1943. This condition usually begins during the first three weeks of life with a sudden loss of weight which may precede obvious gastro-intestinal upset by several days. Pyrexia is not always present but the subsequent course suggests an intense toxæmia or shock. In any particular institution the beginning of such an outbreak may not be explosive, there being intervals of a week or so the first cases. Breast-feeding does not always but the breast-fed infant appears to stand a much chance of survival. Pathological and bac investigations have hitherto proved entirely The only effective measure of control is closure of ward or nursery concerned.

In the outbreak reported in connexion with a matern home at Preston the illness of the 18 fatal cases began varying intervals after discharge from the home, and trouble started as long ago as August. It is not possible to state the case-mortality of this outbre which presents some unusual clinical features that being investigated by a team of pædiatricians.

The illness among infants reported from instituti in several other areas differs clinically from that Leicester or Preston and appears to be much less sev Usually mothers and nursing staff have been affected well as infants. In one outbreak at Hull it is possi though not yet confirmed, that the cause was a salmone

Parliament

QUESTION TIME

Care of Children

Mrs. M. E. NICHOL asked the Prime Minister what st were being taken to implement the interim report of the C of Children Committee on training in child care, which presented last March.—Mr. H MORRISON, Lord Presiden the Council, replied: As soon as the interim report was recei interdepartmental consultations took place and a plan worked out to meet the recommendation of the Curtis Co mittee for a central training council to promote basic train in child care for house mothers. This plan has requi reconsideration in the light of the recommendation in the fi report that the functions of the training council should extended to cover more advanced training for other cla of persons who are concerned with the care of home children. There will be no delay in preparing and giving eff to this revised plan, but while a long-term plan for the train of staff will no doubt be advantageous, it will not meet immediate difficulty caused by the acute shortage of staff children's homes. When an attempt was made last sum to start, in accordance with the suggestion in the int report, a course of training for senior staff it was found that homes were unable to spare any members of their staff for purpose.

Less Bacon and More Milk

Mr. JOHN STRACHEY announced on Dec. 16 that the bac ration would have to be reduced from 3 to 2 oz. on Jan. 5 ne This was the effect of the acute world shortage of cereals, a could only be remedied as that shortage was overcome. the other hand, the non-priority milk allowance to the ordin consumer, which last autumn it was feared might not maintained through the winter at even 2 pints, could increased from 2 to $2^1/_2$ pints on Dec. 22.

Extraction-rates for Flour

Mr. STRACHEY, replying to a question, stated that t following extraction-rates had been current during 1946:

Jan. 1–Feb. 23 ..	80%	Sept. 1–Sept. 21 ..	90
Feb. 24–March 9 ..	$82^1/_2$%	Sept. 22–Sept. 30 ..	85
March 10–May 11 ..	85%	October	85
May 12–June 30 ..	90%	November	85
July	90%	First week of December	85
August	90%		

Penicillin Lozenges

Mr. JOHN LEWIS asked the Minister of Health if he wou prohibit the use of penicillin for the production of lozeng which, apart from civilian requirements, were absorb 250 million units for the Service department requirements, view of the fact that a lozenge containing only 500 units penicillin was useless for the treatment of throat infection.—Mr. C. KEY replied: No, Sir. I am advised that lozenges this strength are quite effective.

Dental Benefit

Commander A. H. P. NOBLE asked the Minister of Nation Insurance whether the Dental Benefit Service had now bee resumed throughout the country following upon his recen ght be accommodated for 10*s.* a day.[2] Up to now, about 00 teachers and students, of 42 different nationalities, have en treated, and the library has grown to 17,000 volumes, art from 150 newspapers and reviews.

Dr. Vauthier now plans a far more ambitious scheme— international sanatorium for tuberculous university idents from any country. This also is to be built at Leysin an altitude of over 4400 ft. above sea-level. It will accomdate 200 sick. The governments of Switzerland, Belgium, d Luxemburg are said to have contributed considerable sums wards the realisation of the project.[3]

AN OFFER TO NEGOTIATE

THE Medical Services Guild, which is a constituent of the nfederation of Health Service Employees, was established n years ago as a section of the National Union of County ficers. All its members must belong to their appropriate ofessional organisation, and its doctors all belong to the M.A. Dr. S. W. Jeger, M.P., chairman of the guild, and r. H. B. W. Morgan, M.P., Dr. Mary Barber, Dr. C. W. rook, Dr. W. W. Fox, and Mr. Denis Whitlock, F.R.C.S.E., ho are all members of its medical advisory committee, ite that it is their "convinced opinion that in the event the B.M.A. leadership refusing to negotiate with the Minister, is incumbent upon the confederation to take a lead in presenting the views of those who voted 'yes' in the cent referendum and we shall, therefore, welcome to memberip all those who think like ourselves."

The confederation was set up this year by the amalgamation the Mental Hospitals and Institutional Workers' Union and e Hospitals and Welfare Services Union, and it has a embership of nearly 50,000. It is affiliated with the Trades nion Congress, and its address is 38, Argyle Square, London, .C.1.

NEW NUTRITION BULLETIN

THE first issue of a new two-monthly *Nutrition Bulletin*, ublished by the Central Council for Health Education, is appear next month. The *Bulletin* will deal not with the sic principles of nutrition but with the application of these rinciples to social betterment. It will thus be concerned with e growth of the various nutrition services, the principles nderlying public instruction, the food habits of the comunity, and the place of diet in the national health. The eoretical literature on applied and social nutrition is also be collected. Articles will be concise, topical, and nonchnical. The *Bulletin's* purpose is to inform all who are irectly or indirectly concerned in improving the nation's iet; and the advisory editorial group will carry on the radition established by the *Bulletin* of the Children's Nutrition ouncil. The annual subscription is 3*s.*; and the council's ddress is Tavistock House, Tavistock Square, London, V.C.1.

HOSPITALS

THE *Hospitals Year Book* for 1946—the fourteenth edition n the series—is now obtainable from the central bureau of nformation of the British Hospitals Association, 52, Green Street, Park Lane, London, W.1. Besides being, as usual, n invaluable work of reference it reviews hospital services uring the last decade and gives an account of the forthcoming National Health Service. As the yearbook went to press efore the Bill became law, a review, by Mr. J. P. Wetenhall, ecretary of the association, of the hospital service under he Act has been published as a separate *memorandum*, which should be useful to those who need a clear accurate ummary of the new provisions.

CLIMATE AND COMFORT

WHAT is the ideal climate? Prof. David Brunt, F.R.S., in lecture to the Royal Institution, has suggested that it hould allow a lightly clothed man to walk at four miles an hour in the sunshine without sweating, and to sit in the unshine and stand or sit in the shade or indoors without hivering. With relative humidity of about 60%, the temperaure, if these conditions are to be met, must be between 6° F and 68° F. For a healthy and active life, the mean temperature of the hottest month should not fall much below 0° F or exceed 70° F or at most 75° F, while in the coldest month it should not become difficult to maintain a comfortable indoor temperature. The largest single area approximately satisfying these criteria is Western Europe; in the British Isles the mean temperature of the hottest month lies between 58° F and 62° F, and that of the coldest month between 39° F and 44° F. Probably the best climate in the world is that of New Zealand, where the temperature in the hottest month varies between 62° F and 70° F, and that of the coldest month between 45° F and 52° F. The hottest temperatures which will allow of any activity are 86° F in air of relative humidity 85%, and 95° F in air of relative humidity 25%. Thus, broadly speaking, dry heat is better tolerated than damp heat; but heat-stroke is not uncommon among those exposed to the hot dry "poison wind" of Arabia—the simoom—which, by promoting excessive secretion and evaporation of sweat, causes exhaustion of the glands.

In England the "optimum" indoor temperature in summer is 66° F, and in winter 62°–64° F, as against 76° F and 72° F, respectively, in the United States. An oppressive damp hot climate, said Professor Brunt, is best countered by the open type of house, permitting free air movement, and, if possible, by drying the indoor air. The dry sunny hot climate, on the other hand, calls for a house with double walls and roof, divided by a wide air space and capable of preventing the intrusion of the hot outer air during the day, when ventilation can be increased by fans.

INDUSTRIAL WELFARE

IN the promising change in outlook now spreading through industry, the Industrial Welfare Society is proving an effective catalyst. The annual report claims that during 1945–46 the society provided the means for the exchange of opinions and experiences; and this is confirmed by the popularity of its conferences and the use made of its information service. A generous interpretation of the Reinstatement in Civil Employment Act has been encouraged, and the fact that very few cases came before the reinstatement committees is evidence of the liberality and careful planning of most firms. Many employers are giving thought to the training of young workers, and are willing to release them for part-time non-vocational education, to establish initiation classes for beginners, to set up works training schools, and to send workers to conferences on industrial topics. Wage questions fall outside the society's scope, but job assessment, job description, and merit rating have been studied closely, and a booklet, "Assessing the Job," has been widely read and approved. The society has also been able to suggest equitable arrangements in problems of works discipline, and has reviewed the works handbooks and rules drawn up by many firms to show workers their rights and obligations.

The report notes that the year has been remarkable for the fact that—despite war-time upheavals, rationing of food and goods, and a change of jobs for a third of the working population—strikes have been relatively few, and industrial relations, measured by the experience of other countries and our own experience after the 1914–18 war, have been good. This, the society considers, has been largely due to the organisation of the trade-union movement. The report emphasises the value, in maintaining these good relations, of careful explanations by the management, including foremen, of the firm's policy, and the reason for this or that action. Several firms which have decided to move their factories to development areas have consulted the society about plans for welfare and personnel departments, and a booklet, "Canteens in Industry," has reached a sixth edition; incidentally, some 450 inquiries about canteens were answered—nearly double the number received in the previous year—and visits were made to 114 firms to advise on special canteen problems. The society has also issued a booklet on cloakrooms, washplaces, and toilets, and has considered seriously the question of colour in industry; the report does not give details on this last subject, but it evidently covers the painting of walls and machines in such a way as to conserve lighting and to throw important and potentially dangerous parts of machines into relief—a practice which can materially reduce accident-rates. Voluntary schemes of insurance against sickness and old age are regarded by the Minister of National Insurance as an important supplement to amounts paid by the State—a principle in which the society is taking a great interest. The Catering Wages Act has raised all-round standards for canteen workers, though the report notes that many members of the society have long given conditions above those laid down by the Act. Personnel and welfare officers have taken an outstanding share in smoothing labour problems in this first year of reconstruction. The report notes that many Service men and women have sought advice from the society about taking up personnel and welfare work, but that "circumstances unfortunately made it [illegible] y of these

3. Palmieri, V. M. *Rif. med.* 1946, 60, 514.

tendent to the Radium Institute, a post which he held till 1923. In 1914 he took his M.R.C.P., and in 1921 his D.M.R.E. at Cambridge. Meanwhile he had broadened his experience in his specialty by serving as an assistant in the electrotherapy department of the Royal Cancer Hospital. Later he took charge of the X-ray department at the Italian Hospital, and was appointed visiting radiologist to the Queen Mary's Hospital, Roehampton, while for twenty years he was associated with the Woolwich Memorial Hospital. His aptitude for able work in all branches of radiology left its mark in all these hospitals, but his published work showed his own main interest to lie in the radiological aspects of tuberculosis and cancer. Well known and liked by his colleagues, he was elected a fellow of the Faculty of Radiologists in 1939, and served a term as president of the electrotherapeutic section of the Royal Society of Medicine. During the war he worked continuously, refusing to take even short respites, and his always indifferent health deteriorated greatly during the last two years. A colleague writes: "Lynham was a man of exquisite charm. On occasion his Irish temperament exerted itself, and he was inclined to be a little impulsive and loved argument; but however his views differed from those of his colleagues he never showed malice towards anyone."

Dr. Lynham married Miss Harriet Hopkins in 1912, and she survives him with a son and daughter.

Diary of the Week

DEC. 29 TO JAN. 4

Wednesday, 1st

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8 P.M. *Surgery* and *Radiology*. Sir Stanford Cade, Dr. J. Ralston Paterson, Mr. W. R. Douglas: Treatment of Carcinoma of the Tongue.

BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, W.1
5 P.M. Prof. W. V. Mayneord: Applications of Atomic Physics in Medicine. (First of six lectures.)

Thursday, 2nd

ROYAL SOCIETY OF MEDICINE
8 P.M. *Neurology*. Prof. E. D. Adrian, F.R.S.: General Principles Governing Nervous Activity. (Hughlings Jackson lecture.)

SOCIALIST MEDICAL ASSOCIATION
7.30 P.M. (296, Vauxhall Bridge Road, S.W.1.) Dr. A. T. M. Wilson: Social Aspects of Medical Psychology.

Friday, 3rd

ROYAL SOCIETY OF MEDICINE
5.30 P.M. *Anæsthetics*. Dr. Ronald Jarman, Dr. Frankis Evans: Anæsthesia for Abdomino-perineal Operations.

Births, Marriages, and Deaths

BIRTHS

ADAMS.—On Dec. 11, at Twickenham, the wife of Dr. G. S. Adams—a son.
CARTER.—On Dec. 16, in London, the wife of Dr. A. B. Carter—a daughter.
JACOBS.—On Dec. 9, in London, the wife of Dr. J. J. M. Jacobs—a son.
LENTON.—On Dec. 12, at Clifton, Bristol, the wife of Mr. P. H. Lenton, F.R.C.S.—a son.
McNEIL.—On Dec. 14, at Poona, India, the wife of Major Charles McNeil R.A.M.C.—a daughter
MASON.—On Dec. 15, at Hull, the wife of Mr. J. I C. Mason, F.R.C.S.—a son.
MINETT.—On Dec 14, at Northampton, the wife of Dr. Jack Minett—a son.
PHILPS.—On Dec. 12, in London, the wife of Dr. Richard Philps—a son.
SIMPSON.—On Dec. 17, in London, the wife of Dr. Thomas Simpson—a son.
SLOAN.—On Dec. 6, at St. Albans, the wife of Dr. Oliver Sloan—a son
TEARE.—On Dec. 13, in London, the wife of Dr. Donald Teare—a son.
TOPHAM.—On Dec. 13, at Edinburgh, the wife of Surgeon Lieut.-Commander L. G. Topham, R.N.—a daughter.
YOUNG.—On Dec. 14, in London, the wife of Dr. W. B. Young—a daughter.

MARRIAGES

ALMENT—BACON.—On Dec. 14, in London, Edward Anthony John Alment, M.R.C.S., to Elizabeth Innes Bacon.
STOTT—CAMPBELL.—On Dec. 7, at Nakuru, Kenya, Hugh Stott, M.B., to Helen Campbell.

DEATHS

DATE.—On Dec. 10, at Radlett, William Horton Date, M.D. Durh., late of Exeter, aged 80.
LYNHAM.—On Dec. 14, at Kingston-on-Thames, John Ernest Albert Lynham, M.D. Belf., M.R.C.P., F.F.R.
SUTTON.—On Dec. 17, at Ventnor, the Rev. Samuel Walter Sutton, M.D. Lond., aged 90.

Notes and News

VIENNA'S FOOD

ON Dec. 17 Dr. Harvey S. Collins, medical consult nutrition to UNRRA, described to a press conferenc nutritional state of Vienna, which he previously rev in May.[1] Examination of over 7000 people, complet Sept. 15, revealed that growth in children was re (particularly in those aged between 7 and 13 years) an adults over 40 years of age were definitely under weigl deterioration increasing with age. Œdema of the was present in 6·3% of a sample population, but in 0·3% was it attributable to malnutrition. Clinical ev of vitamin-B deficiency was rare: 0·8% showed signs su ing riboflavin deficiency, while 6·7% showed signs sugg of nicotinic-acid deficiency; there was no clear evide vitamin-B_1 deficiency. No case of scurvy was recorde vitamin-C deficiency was suggested in 0·62%. Signs, pr due to vitamin-A deficiency, were found in 0·71%. The little indication of vitamin-D deficiency in young ch presumably owing to the distribution of preparations co ing this vitamin and preferential milk distribution.

From the middle of March until early November the ration for the normal consumer remained at 1200 calo day, and the average official ration, taking into ac extras for workers, mothers, and others, was 1440 calo day. Although the allocation of food to Vienna has th been the lowest in any large European community, the been no catastrophe. Probably this is because most c secured just enough extra food to prevent progr deterioration. With the coming of winter, sources of supplies may diminish, as they did last year. This in part at least, be offset by the recent increase of the n consumer's rations to 1550 calories, the maintenance of after the end of this year will rest not with UNRRA but wi Austrian government and the occupying powers.

PROFILES

DOES routine work stifle the creative urge? What right preparation for retirement? The Brains Trus been approached more than once for an answer to searching questions. Maybe the College of Physicians be the better arbiter, at least for the medical man. attractive collection of essays before us speaks for its rather for Sir George Newman.[2] No routine can have more exigent or more protracted than that of the first m officer of the Ministry of Health. But the essays here rep which date from this period of his life reveal the workin a spirit free to roam over the field of nature and the v of truth. The rest of us may reach the same destinati other ways, but here is a modern example of Ga assurance *Eppur si muove*.

All but one of these ten essays appeared anonymou the *Friends Quarterly Examiner* during the forty ye Sir George Newman's editorship. He has now acceded to republication under his own name. They include stud George Fox, Thomas Hodgkin, Joshua Rowntree, R Harris, Jane E. Newman, Joseph Rowntree, and others.

INTERNATIONAL SANATORIUM FOR STUDEN

A QUARTER of a century ago (on Oct. 1, 1922, to be e Dr. L. C. Vauthier opened at Leysin the Swiss Univ Sanatorium, of which he is founder and director, fo treatment of tuberculous teachers and students belongi Swiss universities or technical high-schools Here they ca on their studies at regular hours and in regular doses s to each case, and attended regular lectures from ou teachers. They had a library of 2000 volumes and free a to 15,000 volumes in the Leysin library. A year at the torium counted as a scholastic term. It was claimed the work was good for them, giving them a saner out and preserving them from the demoralising effect of u ployment.[1] This arrangement was made possible by the that all teachers and students in Swiss universities and tech high-schools subscribed (teachers fr. 20, students fr. year) towards a university insurance fund. Any of t contracting tuberculosis could obtain treatment in the S University Sanatorium on payment of the equivalent 36s. a week. If there was room, students from other count

first-class candidates." This seems to be another example of a curious characteristic of our times: all occupations, including medicine, report a shortage of personnel, but those seeking posts are repeatedly baffled by "circumstances" which keep them from work for which they are trained and fitted, or—if they are young—from training for occupations which are crying out for new candidates.

The society's address is 14, *Hobart Place, London, S.W.1.*

University of Cambridge

The following appointments have been made by the university to Addenbrooke's Hospital, from Oct. 1. Mr. N. R Lawrie, PH.D., biochemist; Dr. A. M. Barrett, morbid anatomist and histologist; and Dr. M. H. Gleeson White, bacteriologist.

University of Manchester

The following were successful in recent examinations:

M.B., Ch.B.—*Joan Hampson (second-class honours)*; C. J. T. Archer, Kathleen Burn, H. S. Coulsting, Dorothy R. Davies, Vera A. Dearden, O. G. Dodge, C. J. Glancy, A. B. Haward, J. B. Howard, S. T. Lunt, Joseph Needoff, E. L. Peel, N. W. Preston, Kathleen Rampling, A. E. Shelswell, Lorinda Wallace, Joan M. Waterfall.

University of Edinburgh

The university has replaced the single diploma in radiology, the D.M.R., by two separate diplomas—one in radiodiagnosis and the other in radiotherapy. Candidates are required to attend courses lasting 18 months and 2 years respectively before examination. The university has also established a diploma in industrial health, the course for which lasts one academic year; candidates must have obtained a certificate in public health before starting on the second term of the final course.

Faculty of Radiologists

The following candidates satisfied the board at the recent examination for the fellowship:

R. J. Keating, G. Simon (both in radiodiagnosis).

Royal Medical Foundation of Epsom College

The council will award next March a pension of at least £30 per annum to a necessitous medical man, aged 55 or over, who has been registered for at least five years. Forms of application, obtainable from the Secretary, Epsom College, Surrey, must be returned by Jan. 30.

London Hospitals Amalgamate

Four members of the governing body of Woodside Hospital for Functional Nervous Diseases, Muswell Hill, have been appointed to the board of the Middlesex Hospital. This follows the amalgamation of St. Luke's Hospital Foundation with the Middlesex Hospital, which will thus have 60 additional beds for the treatment of psychological conditions.

Edinburgh Postgraduate Board for Medicine

The following open lectures will be given at the Royal Infirmary on Tuesdays at 5 P.M.: Jan. 14, Prof. F. A. E. Crew, F.R.S., Death in the Blue Book; Jan. 28, Dr. Douglas Guthrie, Is Medicine Still an Art?; Feb. 11, Prof. A. G. Ogilvie, Human Habitat and Social Geography; Feb. 25, Lieut.-Colonel A. D. Stewart, Hospitals and Hospital Administration; and March 11, Prof. J. H. Gaddum, F.R.S., Introduction of New Remedies.

Staffing the Regional Boards

The Ministry of Health has asked local authorities for a statement of the numbers and types of staff employed at central offices or elsewhere for the purposes of their hospital service, or for groups of hospitals, whom they consider likely to be liable to transfer to the regional hospital boards under the National Health Service Act. Replies are asked for by Jan. 31, 1947. A separate inquiry is being addressed by the Board of Control to the authorities concerned with mental-hospital and mental-deficiency services.

Summer Schools in Health Education

The Central Council for Health Education is to hold two residential summer schools next year—one at Keble College, Oxford, from July 25 to August 8, and the other at Bede College, Durham, from August 20 to Sept. 3. The schools are intended primarily for those who have to do with the training and care of children and young people. Inquiries should be directed to the medical adviser and secretary of the council, Tavistock House, Tavistock Square, London, W.C.1.

London County Council

Dr. E. H. R. Harries will retire from the

of the North-Eastern Hospital of the London County in January, when he reaches the age-limit. He has appointment since he entered the service of the L.C.C. and he has also acted as their smallpox consultant sin In 1935 Dr. Harries was Milroy lecturer to the Roya of Physicians, to whose fellowship he was elected His work as a teacher and counsellor has been recognised, and he has served as president of the fe pitals group of the Society of Medical Officers of and on several committees of the Medical Research He is also joint author of *Clinical Practice in I Diseases.*

Empire Rheumatism Council

At the council's annual meeting in London on I Lord Horder, the president, welcomed the annc that the plan for national action, propounded by the in 1941, was to be operated in principle. The that rheumatic patients would no longer be "the f folk" of public-health administration, recorded, a notable achievement which, even if it stood alone, the campaign. In the new health service each region have special treatment centres linked with peripher centres. The council, said Lord Horder, was invest the causes of rheumatoid arthritis. Two whole-time re had been appointed to deal, in the first instance, w cases. If results were encouraging, 1000 cases w studied, possibly with the help of 4 additional re It was hoped that from this survey, started three mont there might emerge lines for specific research.

Appointments

BEATTIE, MYRA K., B.SC., M.D. Belf.: assistant pathologist, Pathological Laboratory, West Park Hospital.
